The *seventh* degree paves the way for the negation of God's unity, which is fully carried out in the *eighth*. Here the Demiurgos, i. e., a second god, but little inferior to the Supreme Being, is the real creator of all things. The first Cause, or the 'Pre-existing,' has neither hands nor attributes; no one is to talk of Him, or to render Him any worship. Much as this part of the doctrine has given cause to discussions within the bosom of the I. themselves, it is yet scarcely doubtful that it is the notion of the Demiurgos that has crept in here. Hamza himself speaks of this 'pre-existence' as the Word, or *Logos* (q. v.), although nothing can be more obscure than the manner in which this most abstruse dogma is either explained or denied by the different doctors. The Koran and the 'Word of God' are then taken in hand, and explained to the proselyte in a fashion very different from the one he had been accustomed to before. The resurrection, the end of the world, the supreme judgment, the distribution of rewards and punishments, are treated as allegorical or mystical symbols of the revolutions of the stars and the universe, which follow each other periodically, and of the destruction and reproduction of all things terrestrial, such as physical science and philosophy teach. The *ninth* and concluding degree of initiation frees the proselyte from all and every restraint with regard to his belief. He may, and some do, adopt the system of Manes (see LARES), of the Magi (q. v.), of Aristotle or Plato, or he may proceed eclectically with them all. As to the notions previously instilled into his mind with regard to the prophets or the Imams, he is now led to look upon all those 'inspired' people as without exception inferior to Mohammed ben Ismail,

the chief and doctor of the last period. The disciple learns, at this stage, that no miracle has ever been performed by any one of them; that the prophet is merely a man distinguished by his purity and the perfection of his intelligence, and that this purity of his intelligence is precisely what is called 'prophecy.' God throws into the prophet's mind what pleases Him, and that is what is understood by 'Word of God.' The prophet clothes this word afterwards with flesh and bones, and communicates it to the creatures. He establishes by this means the systems of religious institutions which appear to him the most advantageous for the ruling of men; but these institutions and behests are but temporary, and intended for the preservation of order and worldly interests. No man who *knows* need practise any single one of them; to him, his *knowledge* suffices.

As to Mohammed, the son of Ismail, of whom the proselyte is told at first that he will reappear in this world—he is afterwards represented to him as merely destined to reappear in his doctrine, by means of the propagation of his pure philosophy by the mouth of his disciples and apostles. As to the Arabs themselves, the missionaries teach that God abhors them, on account of their having killed Husein, the son of Ali, and that he has therefore taken from the califs the Imamatus, as he took from the Israelites the prophetic succession, when they had killed their prophets.

Thus the creed of the I. had been gradually built up. Many changes were introduced into it at different times, and among them, this very important one: That the person of Mohammed, the son of Ismail, itself was changed for another, a descendant of Abdallah, the son of Maimun Kaddah.

The two principal writers on this subject are Makrizi and Nowairi; to the latter of whom the greater part of the foregoing information is due. He has preserved for us at length the very curious oath imposed upon the proselytes at the beginning of the initiation; and also certain instructions reserved for the missionary himself, which simply teach him to 'be all things to all men.' The following is a characteristic sample: 'Then, again, there will be those to whom you must preach the belief in a living Imam. Say Mohammed ben Ismail is alive at this moment. Be very gentle and very modest with them; pretend to despise gold and silver; make them recite fifty prayers a day; recommend them to abstain from lying and other vices, also from wine. These people are of the utmost use to us. Leave them in their special creed, only just telling them some of the mysteries of the number Seven; but break their spirit by the surcharge of prayer. These will be our best proofs against any assertions of an advanced disciple, if he should betray us. Furthermore, these people, when properly managed, are sure to leave you at their death all their money, as they would, during their lifetime, give you everything they possessed without a murmur. The more advanced, you may at once inform of the abrogation of Mohammedanism by our Imam—of the worthlessness of the Koran and its laws in their literal sense. To the still higher disciples, you may confide the entirely spiritual nature of the Imam's "life" in such a manner that their belief in the dogma of the resurrection is practically destroyed by it. From this stage you will conduct some to the renunciation of the belief in the existence of those heavenly beings, the "angels," and the creation of Adam as the first man on earth, while there were many before him. Having arrived at this point, you will find it marvellously easy to destroy the dogma of the existence of God and the mission of angels to

the prophets, and to substitute for all this our own truth—i. e., the eternity of the universe. The last step is the abolition of both Mohammed ben Ismail and Ismail, who are only the "gates" to knowledge.'

So far the doctrines of the I., who, doubtless, aimed—apart from an original desire of purifying and allegorising Mohammedanism, and elevating it to a philosophical system—at political power. How far one of their principal branches, the KARMA-THIANS, succeeded in this, will be found under that heading. See Makrizi, Nowairi, Silvestre de Sacy, *Religion des Druses*, &c.

ITALY. Since the article ITALY was written, the events which are recorded under GERMANY in the SUPPLEMENT, have led to the augmentation of the kingdom of I., by the acquisition of the province of Venetia, with an area of 9709 sq. m., and a pop. of 2,485,989. By the annexation of the Papal States (q. v.) in Oct. 1870, the kingdom of Italy received a further increase of 450 sq. m., with 700,000 inhab.

ITRI, a town of South Italy, in the province of Terra di Lavoro, six miles north-west of Gaeta, picturesquely situated on a lofty isolated hill, surmounted by a ruined castle. I. is the birthplace of the celebrated bandit, Fra Diavolo. Pop. (1861) 6176.

ITU, a town of Brazil, in the province of San Paulo, and 40 miles north-north-west of the town of San Paulo, on the Tiete, in one of the most fertile districts of the province, and surrounded by lofty hills. Most of the houses are built of earth or mud in a framework of wood. Sugar-cane is extensively cultivated in the surrounding district. Pop. 10,000.

ITURBIDE, DON AUGUSTIN DE, Emperor of Mexico, was the son of a Biscayan nobleman and a rich Creole, and was born at Valladolid, in Mexico, in 1784, or, according to others, in 1790. On occasion of the first insurrections in Mexico, he was appointed by the viceroy, Apodaca, to the command of the militia of his province, and was successful against the insurgents; but he afterwards inclined more to their cause, and being intrusted by the viceroy with the command of the army in 1821, he went over to them, when he found it impossible to obtain a separate constitution for Mexico. In May 1822, he ascended the throne of Mexico as emperor, under the name of Augustin I., and the Congress declared the crown hereditary in his family. He seemed to aim at ruling well, but rather as a despotic than a constitutional sovereign. His reign was full of trouble, and came to an end in less than a year by his abdication on March 20, 1823. He received a pension of 25,000 piastres from the Congress on condition of his residing in Italy, and went with his family to Leghorn; but having still many partisans in Mexico, he was induced to return thither in 1824, in order to repossess himself of the throne, and was almost immediately taken prisoner, and shot in Padilla, on July 19 of that year. The Mexican Congress made a provision for his family. His son was adopted by the late Emperor Maximilian of Mexico as his heir, Maximilian himself being childless. The overthrow of the Mexican Empire, however, has cut off his prospect of a throne.

IVANOVO, a town of Russia, in the government of Vladimir, 150 miles west-north-west of Moscow, on the river Ouvod. The name of I. is found in the annals of the 16th century. In 1741, it came into possession of the Counts Sheremetieff, to whom, at the present day, belongs the territory of I., the pop. of which amounts to 24,000. The pop. of the town proper is (1861) 5432. I. is the centre of the Russian cotton manufacture, which gives employment to a great part of the inhabitants, not only of the town,

W. & R. CHAMBERS LONDON & EDINBURGH

Printed and Sold by W. & R. Chambers, Ltd.

but also of the surrounding district. There are also large cotton-printing establishments in the town. The cotton-manufacture of I. has increased to a very considerable extent since 1812, in which year, on account of the French invasion, the greater part

of the workmen left Moscow, and settled here. It is expected that the projected connection of I, by means of a branch, with the Moscow and Nijni-Novgorod Railway, will give a fresh impulse to the industry and commerce of the place.

J

JACITARA PALM (*Desmoncus macroacanthus*), a palm found in the forests of the low lands of the Amazon district in South America. It has a slender flexible stem (see *Desmoncus*), often 60 or 70 feet long.

The outer part of the stem, cut into long strips, is much used for making those very strong and elastic plaited cylinders in which the grated root of the mandioc (cassava or tapioca) is squeezed, to free it from its poisonous juice. It might probably be found useful for many other purposes, and seems eminently suitable for many kinds of wicker-work.

JACOVA, or **YAKOVA**, a town of European Turkey, Albania, in the pashalic of Scutari, on the White Drin, 20 miles north-west of Prisrend. Pop. 18,000.

JA'NKOVATZ, a town of the Austrian Empire, in the Servian Woiwodena, 81 miles south-south-east from Pesh. The surrounding country is level and fertile. Pop. 10,076.

JAULNA, a town of India, in the Deccan, Nizam's dominions, situated on a gently sloping declivity, in a rugged country, 38 miles east of Arungabad. It has a fort and cantonment for British troops. The climate is healthy, and favourable for the production of vegetables and fruits. On the opposite bank is the old town of J., now much decayed, but formerly large and flourishing, having enjoyed an extensive trade in grain and silks. It yet possesses to some extent a manufacture of silks for native use. Pop. 10,000, of whom about a fifth are Mussulmans.

JAVA, THE ISLAND OF. In addition to the information given in the general and special articles on J., the following details seem desirable. In 1864, the pop. of the residencies or governmental divisions amounted to :

| Residencies. | Natives. | Euro-
peans. | Chinese. | Arabs,
&c. | Total. |
|--------------------|------------|-----------------|----------|---------------|------------|
| Bagalen | 863,104 | 309 | 1,836 | 161 | 865,470 |
| Banjoemaas | 688,740 | 440 | 2,748 | 111 | 692,039 |
| Banjoewangi | 42,518 | 110 | 247 | 2,222 | 45,097 |
| Bantam | 604,998 | 238 | 1,628 | 522 | 607,386 |
| Batavia | 463,591 | 5,576 | 47,570 | 1,025 | 517,762 |
| Bezoeki | 315,365 | 404 | 682 | 2,027 | 318,478 |
| Buitenzorg | 350,365 | 491 | 10,345 | 82 | 361,283 |
| Cheribon | 914,161 | 705 | 13,834 | 1,090 | 929,790 |
| Djokjokarta | 368,337 | 1,085 | 1,748 | 148 | 371,318 |
| Japara | 589,338 | 507 | 8,860 | 871 | 599,576 |
| Kadoe | 492,311 | 203 | 3,752 | 64 | 496,332 |
| Kediri | 426,963 | 329 | 3,886 | .. | 431,178 |
| Krawang | 188,834 | 246 | 2,411 | 78 | 191,619 |
| Madicoen | 474,286 | 365 | 1,856 | 153 | 476,630 |
| Pasoeroewan | 488,780 | 955 | 3,332 | 1,515 | 494,582 |

| Tagal | 517,178 | 460 | 3,866 | 1,992 | 523,491 |
| Total | 13,138,806 | 26,680 | 150,632 | 22,604 | 13,338,722 |
| Madura, Island of, | 565,729 | 425 | 5,560 | 6,932 | 578,646 |

Banjoewangi, Buitenzorg, Krawang, and Patjitan are assistant-residencies; Djokjokarta and Surakarta are called the Vorstenlanden (Lands of the Princes), the former having a native sultan, the latter an emperor, who are vassals of the Dutch.

On the 10th of June 1867, an earthquake caused the loss of about 300 lives and a vast amount of property in several of the residencies, especially in Djokjokarta. The mountains are chiefly volcanic. The highest are Sméru or Mahaméru, in the residency Pasoeroewan, which is 12,250 feet high, and Slamant in Tagal, 11,320. Sulphur, almost pure, is abundant.

Bagalen is one of the most fertile residencies, and produces coffee, indigo, tea, cinnamon, rice, tobacco, sugar, maize, cotton, cocoa-nuts, and a great variety of fruits. The forests contain much fine teak. Besides agriculture, the principal industries are weaving, dyeing blue, rope-spinning, making pottery, nets, paper, and mats. In 1855, there were 9,182,519 fruit-bearing coffee-trees, 120 indigo-factories, 4,658,000 tea-plants, and 787,788 cinnamon trees belonging to the government.

Banjoemaas (oe pron. ū) is very mountainous towards the north and north-east. Banjoemaas, the capital of the residency, situated in a valley on the left bank of the Serajo, in 109° 19' 20" E. long, and 7° 33' 45" S. lat., is a regularly built town.

Banjoewangi, an assistant-residency, in the eastern part of the island, is mountainous, well wooded, and fertile. The forests abound in fine timber-trees. Banjoewangi, the capital, lies on the Strait of Bali, in 114° 26' E. long, and 8° 12' 40" S. lat., and is a beautiful little town of 8000 inhabitants.

Bantam, a residency in the west corner of J., is low and marshy on the north coast. Towards the interior, it gradually becomes mountainous, with the most beautiful valleys between the heights. The south coast is wild and rocky, and on the west side are impassable wildernesses, swarming with wild beasts. The soil is generally fertile, producing the usual crops of the island. Bantam, the former capital of the once powerful kingdom of that name, is now little more than a village, in which the remains of former grandeur are to be seen. The resident has his seat at Serang, a large village, in 106° 8' 37" E. long, and 6° 6' 45" S. lat.

Bezoeki, on the east coast, is mountainous, and clothed with a luxuriant vegetation.

Buitenzorg, an assistant-residency, is very healthy, and often has a favourable influence on the sick from other districts of J., especially of Batavia, to which it is contiguous. Buitenzorg, the capital, is 833 feet above the sea-level, and is one of the most pleasant places in the island.

Cheribon is a very extensive and beautiful residency, and derives its name from that of the capital, which is a corruption of Tji-ribon, or river Ribon, on which it is built. Cheribon, the capital, in 108° 38' E. long., and 6° 45' S. lat., was once a flourishing place, but has been for some time retrograding.

Djokjokarta produces the usual crops. The natives are much addicted to the use of opium. The productive power of the population is therefore less than in other districts of the island.

Djokjokarta, the capital, is situated on the right bank of the Oepak, in $110^{\circ} 21' 30''$ E. long., and $7^{\circ} 46'$ S. lat., at the south-south-west base of the mountain Merapi. The city is large, and regularly built. It is the seat of the sultan, the resident, and assistant-resident. Pop. 50,000, of whom 600 are Europeans.

Japara, on the north coast, has a very warm climate in the interior, and though vegetation is in general luxuriant, yet scarcity of water is sometimes felt. The resident has his seat at Pati, in $110^{\circ} 56' 7''$ E. long., and $6^{\circ} 45' 30''$ S. lat., which is regularly built, and has a pop. of 10,000.

Kadoc—i. e., hollow—is a large basin formed by lofty mountains, of which Soembing is 10,911 feet high, and the Sindoro 10,312. It is one of the smallest residencies of J., but densely peopled. Its fertility is increased by the abundance of water flowing from the surrounding mountains. The amount of coffee produced is very great; in 1853, the fruit-bearing trees numbering 30,937,695. Beautiful marble is found in great quantities. The capital is Magelang, situated on the east bank of the Progo, in $110^{\circ} 10' 7''$ E. long., and $7^{\circ} 29'$ S. lat. Pop. 34,000.

Kediri consists of a plain bounded by mountains on the north, east, and west. The navigable river Brantas, which flows through a great part of the residency before falling into the sea at Surabaya, affords great trading facilities. The people, however, are low in the scale of activity and morality, which may partly result from Kediri having been, under the former Javan princes, a penal colony. They are greater slaves to opium than any other people in the Indian Archipelago. Kediri, the seat of the resident, is situated on the right bank of the river Kediri, 600 feet broad, which higher up is called the Brantas. The streets are broad and planted on both sides with tamarind trees.

Paseroewan, which is washed by the Strait of Madura, has important fisheries, and is famed for its race of horses. Paseroewan, the capital of the residency, is situated near the sea, on the river Gembong, in $112^{\circ} 55' 2''$ E. long., and $7^{\circ} 38' 40''$ S. lat.

The Preanger Regencies are partly occupied with mountains, forming two chains. Between these are many extensive valleys of the richest soil. The mountains are of basalt. There are many rivers, of which five are navigable. The numerous lakes give good supplies of fish and water-fowls. The bays on the coast are also frequented by fishing-boats. The mountains are covered with coffee plantations to 3000 feet above the sea-level, while the low and marshy grounds produce rice abundantly, and the villages are hid with cocoa-nut palms and other fruit-trees. In no other residency is the tea-culture so extensive. The forests produce good timber, the bamboo attaining a height of 80 feet. There are rhinoceroses, tigers, harts, wild swine, &c., and birds of great variety and beauty. The natives are honourable, simple, and obedient, and subsist from the growing of coffee, rice, fruits, &c., the rearing of horses and buffaloes, making spinning-wheels, mats, gold and silver work, &c. The women weave very beautiful cotton-cloth. Coffee and tea, and later, also cinchona, are the only products raised for the government.

Probolinggo is fertile, and produces good crops of rice, coffee, and sugar. The south coast is covered with forests, which contain many teak trees. There are tigers, wild dogs, monkeys, squirrels, &c. Probolinggo, the capital of the residency, lies on the coast, in $109^{\circ} 21' 45''$ E. long., and $7^{\circ} 23' 22''$ S. lat., and is extensive and populous. From this port, much of the produce of the land is shipped for the Netherlands.

Rembang produces the usual crops. The northern parts are dry and sandy; and in the south are extensive forests, abounding in teak and other valuable timber trees. The residency is washed by the Java Sea, and the people on the coast find their living by trade, fishing, and ship-building. Rembang, the capital, is regularly built, and besides the public offices, has a small Protestant church, a government school, and an institution for the education of girls.

See SAMARANG, SURABAYA, and SURAKABTA.

Tagal is very fertile. It is washed on the north by the Java Sea, and the fisheries are important. In the south of the residency is the volcano Slamet, 11,320 feet high, which is clothed with forest to the height of 8500 feet, and on the southern side descends by regular terraces to the bed of the river Serajoe. Tagal, the capital, is a small but neatly built town, with a considerable coasting-trade. The natives are industrious and good handicraftsmen.

JAWOROW, a town of the Austrian Empire, in the province of East Galicia, 28 miles north-west from Lemberg, on the Krakowska, an affluent of the San, which itself is a branch of the Vistula. Close by the town is a lake, abounding in fish. J. is built in the form of a square, and has extensive suburbs. It has mineral springs. Near it are large paper-mills. Many of the inhabitants are Jews. Pop. 7209.

JAY, WILLIAM, an English Independent or Congregational minister, of much celebrity for his pulpit eloquence, and as a voluminous writer of devotional, practical, and other religious works. He was born, May 8, 1769, at Tisbury, in Wiltshire. His father was a stone-cutter and mason, and young Jay's first employment was that of a mason's boy; but whilst still young he was sent to Marlborough Academy, an institution of the Congregationalists for the training of young men for the ministry. According to a custom prevalent amongst the Congregationalists, he was sent out to preach in country villages almost in his boyhood—in fact, before he was 16 years of age. His education being completed, he officiated for a year in a chapel at Clifton; and in 1791, was settled as pastor of a 'church' in Bath, which position he occupied for 62 years. He retired from it in January 1853, and died on December 27 of the same year, at the age of 84. Mr Jay's published works, in general, attained to a rapid and very extensive popularity. Among them are *Sermons*, *Family Prayers*, *Morning and Evening Exercises*, *Mornings with Jesus*, an *Essay on Marriage*, *Memoirs of the Rev. Cornelius Winter*, *Memoirs of the Rev. John Clark*, *Lectures on Female Scripture Characters*, and an *Autobiography*. A collected edition of his works, in 12 vols., revised by himself, was published in 1841, but is of course incomplete, some of his works being of more recent date.

JEISK, or EISK, a town of Russia, in the country of the Kuban Cossacks, or Black Sea Cossacks, on the eastern shore of the Sea of Azov, 60 miles south-west from Azov. It stands on the shore of a small land-locked bay, into which flows the river Jeisk. It was founded by imperial ukase in 1848, with a view to its being a trading seaport, and an entrepôt for the agricultural produce of the surrounding country. Considerable privileges were guaranteed to its inhabitants, and it has rapidly sprung into importance. Pop. (1863) 16,747.

JESI, or IESI (anc. *Æsium*, or *Æsis*), a prosperous manufacturing town of Central Italy, in the province of Ancona, and 15 miles south-west of the city of Ancona, on the left bank of the river Esina. It is surrounded by walls, has a cathedral, and several other churches and convents. It has manufactures of paper, silk, and

woollen hosiery and linen, and a large trade in wine and olives. J. is the birthplace of the German emperor Frederick II. Pop. (1861) 11,469.

JEW'S EAR (*Ecidium auricula Judæ*), a fungus, one of the *Hymenomyces*, which grows on decaying parts of living trees, particularly elders. It is a native of Britain. In size and form it bears some resemblance to a human ear. It is soft but cartilaginous, wrinkled, and generally brown. It is stemless. The spores are produced on the upper surface. The under surface is fibrous and downy. J. E. was formerly in repute as a topical discutient and astringent. It may be kept long in a dried state. It is still sold in the shops, but *Polyporus versicolor* is often substituted for it. The genuine J. E., after being dried, swells when immersed in water; the *Polyporus* does not.

JIKADAZE, or **SHIKATZE**, a town of Tibet, capital of the district Zang, on the right bank of the Zangbo, 190 miles west of Lassa. Pop. estimated at 100,000.

JIMENA, or **XIMENA**, a town of Spain, in the province, and 50 miles east of Cadiz, on the east declivity of the Sierra de Gazules. The town is regularly built, the streets steep, but clean. There are several churches and schools, a prison, town-house, &c. There are manufactures of leather, linen, earthenware, &c., and a trade in fruit and wine. Pop. 5878.

JOACHIM, **JOSEPH**, an eminent Hungarian violinist, was born in the neighbourhood of Presburg in 1830, received his early instruction at Pesth under Szervawinsky, director of the orchestra at the theatre there, and made his debut in public at the age of seven. He afterwards became the pupil of Böhm at Vienna, and at Leipzig studied counterpoint under Hauptmann, and made the friendship of Mendelssohn. His first appearance in London was in 1844, when, though only in his 14th year, he was at once allowed to be one of the most distinguished of contemporary violinists. His performances at Vienna, Pesth, Paris, and London have since established for him the position of the first violinist of the day. In power and brilliancy of execution, and all the mechanical qualities of playing, he is little if at all behind Paganini; while in the intellectual qualities, he far surpasses that artiste, and possesses, in an almost unequalled degree, the faculty of seizing instinctively the idea of the composer. His works, which include overtures, Hebrew melodies and other songs, and compositions for the violin, are pervaded by the same tenderness and depth of musical feeling that characterise his playing.

JOACHIMSTHAL, a town of Bohemia, near the frontier of Saxony, 69 miles west-north-west from Prague. It is situated in a valley, on the Weseritz, a feeder of the Eger, which itself flows into the Elbe, near the eastern opening of a remarkable gorge or pass among the lofty Erzgebirge, and at an elevation of 2366 feet above the sea. The town has a strange antique appearance, and the Rathhaus is a very remarkable building. J. was formerly of greater importance than now, owing to its mines of silver, which are still wrought, but are not so productive as they once were. The produce of the silver-mines of J. in the 16th c. was, at an average, 21,897 marks. For about a century before 1852, the average produce was only 3181 marks; and from 1852 to 1862, it was 3232 marks. Silver-mines have been wrought at J. from a very remote period; one mine is 300 fathoms deep. The whole number of miners employed at J. in the 16th c. was about 12,000, with 400 overseers and other

officials, and 800 surveyors. Besides the silver obtained from the mines of this neighbourhood, it produces also lead, tin, and iron to a considerable amount. J. is the seat of offices and courts of mines. Dollars (*thalers*) were first coined here, and hence their name (see DOLLAR). Goitre and cretinism are lamentably prevalent at Joachimsthal. Much coarse lace is made in the surrounding mountainous district. Pop. 5641.

JOE MILLER'S JESTS, or the **WIT'S VADE-MECUM**, a well-known collection of facetiæ, first published in 1739. A great proportion of the good things which this book contained appears to have been the product of the period immediately preceding its publication. They are more often humorous than witty, and they seem to have been all the more popular on account of a profusion of coarseness and indecency, such as the taste of the present age could not endure. A second edition of the *Jests* was called for in the year of the first publication; they came to a fourth edition in the following year; and the work, growing in size at every fresh appearance, had reached its 14th edition by 1760. Innumerable issues of it, or of works founded upon it, bearing the same or similar titles, have since been published in England and America. It has, in many cases, been modified more or less, to suit the growing nicety of the public—with detriment, it must be said, to the quality of its humour; and, indeed, it would almost seem as if humour flourished upon obscenity as flowers do upon manure. A lithographic fac-simile of the first edition, which is now exceedingly rare—there is no copy in the British Museum—was published in 1861. The exact title was as follows: '*Joe Miller's Jests, or the Wit's Vade-mecum; being a Collection of the most Brilliant Jests, the Politest Repartees, the most Elegant Bons-mots, and most Pleasant Short Stories in the English Language.* First carefully collected in the Company, and many of them transcribed from the Mouth, of the Facetious Gentleman whose name they bear; and now set forth and published by his Lamentable Friend and Former Companion, Elijah Jenkins, Esq.; most humbly inscribed to those Choice Spirits of the Age, Captain Bodens, Mr Alexander Pope, Mr Professor Lacy, Mr Orator Henley, and Job Baker, the Kettle-drummer. London, T. Read, Dogwell Court, Whitefriars, Fleet Street, 1739.'

The Joe Miller whose name has been handed down in connection with this compilation of jests was Joseph Miller, an eminent comic actor, reputed among the tavern-haunters of his time as a fellow of infinite humour. He was born, it is believed, in London, in 1684; he died in London in 1738, and was buried in the churchyard of St Clement Danes in the Strand, where there is a tombstone erected to his memory, bearing an epitaph by Stephen Duck. He was a great favourite with the public, and is said to have contributed by his acting to the popularity of Congreve's plays. Ben in *Love for Love*, Sir Joseph Wittol in the *Old Bachelor*, and Teague in the *Committee*, were the characters in which he was most successful; his portrait was painted in the last two of these. The compiler of the *Jests* was John Mottley, an author of no great reputation, who is said to have amused himself by writing down or dictating them at a time when he was laid up with the gout. Mottley was the son of a Colonel Mottley, who, having been high in favour with James II., followed James into exile, got a command in the service of Louis XIV., and was killed at the battle of Turin in 1708. Colonel Mottley had married before the Revolution a Gloucestershire lady of considerable fortune. His wife—her family being zealous for the Revolution—

refused to accompany him to St Germain. Three or four years later, he made a stay of considerable length in England upon a secret commission from James; and his son, the compiler of the *Jests*, was born in London in 1692. Mottley was educated at St Martin's Library-school in London; and, through the influence of Viscount Howe, who was a connection of his mother, he got, at the age of sixteen, a place in the Excise Office. This place he lost in 1720, apparently through some involvement in the bubble speculations of that year; and afterwards, though he had promises both from Lord Halifax and from Sir Robert Walpole, he never succeeded in obtaining an office. He had to live by his wits, and he produced five or six plays—the first of them named the *Imperial Captive*—which met with some success. He seems to have owed not a little to the patronage he received from people of fashion and from the court. In 1739, the year in which he produced *Joe Miller's Jests*, he also published a *Life of the great Czar Peter*, in 3 vols. 8vo. This work was published by subscription, and had the support of the royal family, and of a great number of the nobility and gentry. He followed it up in 1744 with the *History of the Life and Reign of the Empress Catharine of Russia*, 2 vols. 8vo. These works were mere compilations from the journals and other publications of the time; but with the lapse of time they have acquired some value, through the scarcity or disappearance of the authorities upon which they were founded. Mottley died on the 3d of October 1750.

JOHNSON, ANDREW, seventeenth President of the United States of America, was born at Raleigh, North Carolina, December 29, 1808. At the age of four years, he lost his father, who was drowned in attempting to save the life of a friend; and when ten years old, he was apprenticed to a tailor, whom he served for seven years, receiving no schooling. A visitor to the shop where he worked used to read aloud from a collection of speeches of British statesmen. This aroused young J.'s interest and ambition; he learned the alphabet, borrowed the book, and with the aid of a journeyman, learned to read, working at it two or three hours every night. At the expiration of his apprenticeship, he worked for two years as a journeyman at Laurens Court House, South Carolina; but a love-disappointment, caused by his humble position, induced him in 1826 to emigrate to Greenville, Tennessee, where he soon after married, and his wife taught him writing and arithmetic. In 1828, he was elected to his first office—alderman of the village; in 1830, he was chosen mayor, and twice re-elected; in 1835, he was elected to the state legislature, and again in 1839; in 1840, he was a presidential elector, and canvassed the state for Mr Van Buren, the Democratic candidate; in 1841, he was elected to the state senate; and in 1843, to the Congress of the United States, where for ten years he supported the policy of the Democratic party. In 1853, he was elected governor of Tennessee, and again in 1855. In 1857, he was elected by the legislature a member of the United States Senate, in which he advocated the union policy of the Republican party; and on the occupation of Nashville by the Federals, 1862, was appointed by President Lincoln military governor of Tennessee. In this position he gave so much satisfaction to the North, that in 1864 he was nominated by the Republican party for the office of vice-president, and was elected with President Lincoln, then re-elected for his second term, and took the oath of office, March 4, 1865. On the 14th of April, by the assassination of President Lincoln, he succeeded to the presidency, but soon disappointed his party by taking a

moderate, conservative course, scrupulously respecting his oath to support the constitution, pardoning great numbers of rebels, and opposing his veto to many bills passed by Congress to hinder the reconstruction of the South on the principles of its former constitutional representation. In 1866, his policy appeared for a time likely to meet with popular favour; but some indiscreet and violent speeches, during a tour to Chicago and St Louis, turned the tide against him, and in the congressional elections his opponents triumphed by increased majorities. His vetoes were generally nullified by the two-thirds votes of both Houses, and the President was threatened by the Radicals with impeachment and deposition. A majority of a committee of Congress, appointed to consider the matter, actually recommended his impeachment; but Congress (December 1867), by a large majority, decided not to act on the recommendation.

JOONAGHU'R, a town of India, province of Gujerat, on the peninsula of Kattywar, 235 miles north-west of Bombay. It is advantageously situated on a ridge of sandstone, is surrounded by walls five miles in circumference, and has a citadel and a mosque. The town is ill built and dirty, and only about a half of the space within the walls is occupied. The trade is insignificant. Pop. variously estimated at from 5000 to 30,000.

JUAREZ, BENTO, President of the Mexican Republic, was born at Ixtlan, of Indian parents, about the year 1807. Notwithstanding the disadvantages of birth, he succeeded in establishing a reputation as an advocate, became governor of his native state, Oaxaca (1848—1852), and an active member of the liberal party. Exiled during the dictatorship of Santa Anna, he returned when the republic was restored, was elected to the new congress (1856), and appointed President of the Supreme Court in 1857, and consequently, in case of vacancy by death or default, President *ad interim* of the republic.

On the overthrow of the liberal President, Comonfort, by Zuloaga and the clerical party (January 1858), J. refused to recognise the usurper, and finally established himself at Vera Cruz, by holding which he secured the receipt of the customs dues—in other words, of the larger half of the entire state revenue. Here he set up a provisional government, styling himself Constitutional President, and issuing decrees for the confiscation of the property of the church, the institution of civil marriage, &c., in accordance with the reforms carried by Comonfort in 1857. Meanwhile, Miramon, who had superseded Zuloaga (January 1859), prepared to take the field against his rival. His movements were, however, delayed by a counter-rising of Juarists in Mexico; and before he again advanced, J. had secured recognition from the United States by conceding the protectorate (refused to them by Miramon) over the proposed transit routes in the north and in the isthmus of Tehuantepec. Early in 1860, Miramon besieged Vera Cruz, but his army suffered from want of supplies, his transports were intercepted by the United States ship-of-war *Saratoga*, and after a few weeks, he was compelled to retire with loss. J. now assumed the offensive. At San Miguelito, Miramon was totally defeated by Ortega, and fled to Europe. His rival entered Mexico (January 1861), caused himself in June to be formally elected president for four years, and proceeded to execute the decrees against the clergy with great severity. But the finances of Mexico were now in a state of disorder, which even the wholesale confiscation of church lands could not remedy. In July 1861, the government decreed

suspension of payment for two years of the indemnities due to England and France, and formally secured by the hypothecation of the customs dues. This act, coming at the end of a long series of outrages (mainly the work of Miramon and his faction), led to the intervention of the allied powers, and the occupation of Vera Cruz by England, France, and Spain. But it soon appeared that the French aimed at more than a simple redress of grievances. The appearance of the clerical chiefs Miramon and Almonte in their camp, and the extravagant demands of M. de Soligny, rendered any arrangement impossible. The failure of the negotiations at Soledad (February 1862) was followed by the conference of Orizaba (April 9), in which England and Spain formally withdrew. France now threw off the mask, and J. appealed to the country, proclaiming a guerrilla war, and concluding a loan of 25,000,000 dollars with the American minister, Corwyn. The victory of Zaragoza at Puebla (May 5, 1862) raised the hopes of the Mexicans; but fresh troops arrived from France. Puebla fell (May 18, 1863), after a gallant resistance. Mexico and San Luis de Potosi followed, and in 1864 the republican government was removed to Monterey. The arrival of Maximilian in May was succeeded by further losses from battle and desertion. In August, J. sent his family to New Orleans, but 'le petit Indien' himself still held on, although forced back on Chihuahua, and thence a year after across the frontier. His four years of office had also expired, and Maximilian availed himself of these events to issue the fatal decree of October 1865, in which he declared the republic extinct *de jure et de facto*, and sentenced to death all Juarist leaders taken in arms. J. proclaimed in answer that he held office until the expulsion of the invaders rendered a fresh election practicable. By this time the complete pacification of the Southern States enabled the Washington cabinet (which had persistently recognised J.) to interfere effectually on his behalf. Under diplomatic pressure (1866), Napoleon withdrew his troops, and the positions evacuated by the French were immediately occupied by the republicans. The unhappy Maximilian made a final stand in Queretaro, but was betrayed by Lopez, and shot (June 19, 1867) by order of court-martial—an ungenerous but not unjustifiable act of reprisal which J., it is said, would have been unable to prevent. Mexico and Vera Cruz were reoccupied shortly after, and the triumph of the liberals was consummated by the re-election of J. to the presidency (October 1867), after a ten years' struggle, in which he had successfully maintained the constitution of 1857, under which he took office, against domestic treason and foreign intervention. There is much reason to hope that J., who, as governor of Oaxaca, was universally esteemed, and whose honesty as a reformer has been attested by the British chargé d'affaires (Mr Mathew's Report, 1861), and by all the leading men in the United States, will inaugurate a new era in Mexico of progress and tranquillity.

JUJUY, a town of the Argentine Confederation, South America, on a river of the same name, about 300 miles north-north-west of Santiago. It is said to be a place of some trade, being on the main route from Salta across the mountains into Bolivia. Pop. (1860) 6900.

JULALPUR, a town of India, capital of the pergunnah of the same name, 100 miles south-west of Lucknow, on the river Betwa. It is said to be a place of some importance, and to contain a pop. of 10,000. The country to the south is wild and sterile, being much cut up by ravines.

JULIA, the only child of the Roman emperor Augustus, was his daughter by his second wife, Scribonia, and was born 39 B.C. She was only a few days old when her mother was divorced. She was educated with great strictness; was distinguished for her beauty, talents, accomplishments, and agreeable manners; and was married at a very early age, 25 B.C., to her cousin, Marcus Claudius Marcellus, the sister's son of Augustus. After his death, she was again married, when little more than 17 years of age, to Marcus Vipsanius Agrippa, to whom she bore three sons and two daughters. He dying, 12 B.C., J. was given in marriage, 11 B.C., to Tiberius; his mother, Livia, the stepmother of J., persuading Augustus to this, in order to secure the succession of Tiberius to the throne. The marriage was an unhappy one, and the conduct of J. far from irreproachable; but Livia's hatred induced her to make exaggerated accusations to Augustus, and she so wrought upon his mind, that he astonished all Rome by suddenly declaring, 2 B.C., that his daughter had so far forgotten herself as to be guilty of the most shameless adulteries, making even the Forum the scene of her nightly vice. In this charge there seems to have been too much truth; but it is doubtful if there was any truth in the allegation further made that J. and her paramours had entered into a conspiracy against the life of the emperor. J. was banished to the isle of Pandataria (now Ventotiene), near Naples, and a number of persons of high rank were put to death or banished for their alleged participation in her guilt. From Pandataria, whither her mother, Scribonia, accompanied her, she was removed to Rhegium (now Reggio), where she was allowed by Tiberius to remain destitute even of common comforts, till her death, 14 A.D. Her son, Agrippa, was put to death by Tiberius in 14 A.D., shortly before the death of his mother. Her other sons died in early age. Her daughters survived her. The elder, Julia, died, 28 A.D., in the isle of Trimetus, on the coast of Apulia, whither she had been banished by Augustus twenty years before for adultery. The younger, the virtuous Agrippina (q. v.) died in 33 A.D., in Pandataria, to which she had been banished by Tiberius.

JULICH, or, in the French form of the name, JULIERS, a town of Rhenish Prussia, 16 miles north-east from Aix-la-Chapelle, on the Roer. J. is situated in a fertile plain, but surrounded by marshes, which make it very unhealthy. It is said to be of Roman origin, and was strongly fortified till 1860, when the fortifications were demolished. The principal branch of industry is the manufacture of leather. Pop. (1864) 5244.—J. was long the capital of an independent duchy; and J. and Berg (q. v.) were united as possessions of the same family. On the death of the Duke of J. in 1609, began a dispute as to the succession, which was not settled till 1666, when a decision was given in favour of the House of Pfalz-Neuburg—the Elector of Brandenburg obtaining Cleves and some of the other territories formerly united with J. and Berg. The Pfalz-Neuburg family becoming extinct in 1742, J. passed to the Pfalz-Salzbach branch, afterwards electors of Bavaria. By the peace of Luneville, it was annexed to France, as part of the dep. of Roer; and in 1814, was assigned to Prussia by the Congress of Vienna.

JUMPING HARE (*Pedetes* or *Helamys Capensis*), a South African rodent, *Spring Haas* of the Dutch colonists, generally placed near the jerboas in systems of zoology, but very considerably differing from them. The head much resembles that of

JUNGLE—JUTE MANUFACTURES.

a hare, although the ears are shorter; the form of the body is also like that of a hare, but the hind-legs are very long and strong, like those of a kangaroo, and the toes both of fore and hind feet are armed with great claws. Its powers of leaping are

Jumping Hare (*Helamys Capensis*).

extraordinary; it clears 20 or 30 feet at a bound. Night is its time of activity, and it makes mischievous inroads on fields and gardens. Its flesh is eaten.

JUNGLE, a term now fully adopted into the English language, but of Bengalese origin, and employed to designate those thickets of trees, shrubs, and reeds, which abound in many parts of India, and particularly in the unhealthy tract called Terai or Tarayani, along the southern base of the Himalaya; and in the Sunderbunds (q. v.) at the mouth of the Ganges. The jungles are often impassable, from the thick growth of underwood, tall grasses, and climbing plants. The soil is generally swampy, and fever and other diseases abound. Tigers, and other beasts of prey, elephants, boars, deer, and other quadrupeds are found in great numbers in these thickets, with gigantic snakes, and multitudes of monkeys. The jungle flora and fauna are very peculiar, and the moisture and heat carry a tropical vegetation beyond its usual limits northward to the lower valleys of the Himalaya.

JUNGLY GAU (*Bos Sylhetanus*), a species of ox, inhabiting Sylhet and other mountainous parts of the north-east of India. It is nearly allied to the Gayal (q. v.) and to the common ox, and has more the appearance of some of the European domesticated breeds of ox than any of the other wild oxen of Asia. The J. G., although in a wild state it is only to be seen in places remote from the habitations of man, and flees from the encroachments of cultivation, is easily domesticated. Its milk is very abundant, and of excellent quality.

JUTE MANUFACTURES. The extensive and daily increasing use of jute as a textile material, has induced us to give a brief notice of its manufacture into fabrics, by way of supplementing what has been already said under the head **JUTE**. This now gigantic industry has sprung up so rapidly, one might almost say so stealthily, that comparatively few persons are aware of its importance, and many have never even heard of the fibre at all. For some thirty years back, the Dundee mill-owners have been gradually employing it more and more to mix with flax, until there is scarcely one of them who does not use it largely, and the majority now use it entirely. Jute is more brittle than flax, and will

not spin so fine, nor wear so well; but then it is only about half the price, and when woven, is attractive enough in appearance. In India, it has been manufactured by the natives into gunny-cloth for centuries.

The jute-plant is very largely cultivated in Bengal, and the fibre is prepared there for exportation by the process of water-retting. Jute of a fine glossy appearance brings the highest price in the market. It is spun by processes similar to those employed for flax, but as it is from 10 to 15 feet long, it is necessary to cut it into 3-foot lengths before it can be heckled. The fibre also requires to be saturated with whale-oil and water, so as to soften and render it more elastic, preparatory to spinning. Heckling is the first of the spinning operations, and its object is to remove the coarser portions of the jute, and lay the fibres in parallel order. The heckle is a kind of comb, with sharp-pointed steel teeth, from one to two inches in length. Formerly, the process was done by hand, but now heckling-machines are used. The heckled stricks are next taken to the *spreader*, or first drawing-frame, where they are spread upon an endless creeping-sheet, so as to supply the jute continuously to another part of the machine, where, by a peculiar arrangement of rollers, it is drawn out, through combs of closely-ranged steel pins, into a continuous ribbon, called a *sliver*. A number—say, 14—of these slivers are then taken to another drawing-machine, with steel combs, and drawn out into one. In like manner, some 20 of these slivers are again drawn into one. The first sliver from the spreader has thus, so to speak, been drawn out 280

Jute (*Corchorus capsularis*):
a, capsule; b, flower.

times its original length; and by this means the fibres become thoroughly parallel and equalised. The sliver from the last drawing-frame is still further drawn out, and at the same time receives a slight twist in the roving-frame. Finally, the bobbins of 'rove' are taken to the spinning-frame, and spun into yarn upon the 'throstle' principle.

Just as in the case of flax, the jute tow from the heckling process is also spun into yarn, in which case it is first carded by means of a 'breaker' and

'finisher' card, and then *drawn, roved, and spun*, as above described. Indeed, a great deal of jute, as imported, is treated in this way without being heckled at all.

The larger portion of jute fabrics are woven from yarn of the natural colour; but for some purposes it is bleached; and when used for carpets, it is dyed various colours. It bleaches with difficulty, but it is easily dyed. Among the various kinds of jute-cloth made, hessian sheetings for packing all kinds of merchandise are most largely produced; but sackings, baggings, osnaburgs, ducks, carpetings, matting, and several other stuffs are likewise extensively manufactured. It is also intermixed with flax, cotton, and wool for various union fabrics. Jute carpets are produced at a wonderfully low price, viz., from 7d. to 1s. 3d. per yard. The better qualities of these are comfortable, and even beautiful, so long as they keep their colour; but herein lies their great defect, since all dyes have hitherto been found to be comparatively fugitive upon jute. It is affirmed that some colours can now be rendered permanent by a new process of dyeing them. If so, a wide field will be opened for the development of this branch of the trade.

For many years after the introduction of jute in 1833, Dundee was the only place in Great Britain

where it was manufactured; but now, considerable quantities of jute goods are made in London, Manchester, and Glasgow. Of late, several large works have been erected in Calcutta for spinning and weaving jute by English machinery. Dundee is still, however, the great centre of the trade; and there the consignment of the raw material, which, in 1836, was only 300 tons, will this year (1867) be about 65,000 tons, or 500,000 bales. The number of persons employed in its manufacture in that town is upwards of 30,000, and it will give an idea of the vast size of some of the larger jute-mills to state that, in the one belonging to Messrs Cox Brothers, there are between 20 and 30 steam-engines, most of them of considerable size. In one of the weaving-rooms of this mill there are 860 power-looms; and like several of the large Dundee factories, it contains within itself an iron foundry, a smithy, fitting-shops, and, in short, all the departments of an extensive engineering establishment.

The total quantity of jute and jute-bagging exported from India in 1866 was 80,908 tons, which was valued at £1,499,533. In 1864 and 1865, considerably larger quantities were exported. A little of this was sent to France and Holland, but about nine-tenths of it was imported into the United Kingdom.

K

KADOM, a town of Russia, in the government of Tambov, and 140 miles north-north-east of the town of Tambov, on the river Moahka. The houses are built chiefly of wood, and the principal trade is in honey. Pop., mostly of Tartar descent, 7173.

KAKA'PO, or **OWL PARROT** (*Strigops habroptilus*), a remarkable bird, a native of New Zealand, belonging to the Parrot family (*Psittacidae*), but of very owl-like appearance,

Kakapo (*Strigops habroptilus*).

and, like the owls, nocturnal, or nearly so, concealing itself in holes during the day, except in very

gloomy weather. The K. takes possession of a hole, where one exists, among stones or the roots of trees, but seems also to have the power of making a burrow for itself. Dogs take it in its hole, although it makes some resistance; but, after a little experience, they learn how to deal with it. It is also pursued and taken by dogs when running on the ground. The flesh of the K. is more pleasant and delicate than that of any other parrot. This interesting bird has almost disappeared from the northern island of New Zealand, and is much more rare in the middle island than it was not many years ago. It will probably soon be extinct, unless means are adopted for its protection. It is the only known bird having large wings which does not use them for flight.

KANGAROO APPLE, a species of *Solanum* (q. v.), (*S. laciniatum*), with a somewhat shrubby succulent stem, smooth pinnatifid or entire leaves, and lateral racemes of flowers; a native of Peru, New Zealand, Australia, and Tasmania, in which latter countries its fruit is called kangaroo apple, and is used as food. When unripe, it is acrid, and produces a burning sensation in the throat; but when perfectly ripe, it is wholesome.

KA'NIZSA, the name of two towns in Hungary. —K. Nagy, a market-town, and once an important fortress, in the county of Szalad, 120 miles south of Vienna, with which it is connected by railway. It has several churches, a monastery, town-house, &c. There is a considerable trade in cattle. Pop. 11,722. —K. Magyar, a market-town in the county of Bacs, in a fertile district on the Theiss, 15 miles south-south-east of Szegedin. It has several churches, a synagogue, high school, &c., and a trade in corn and cattle. Pop. 8855.

KA'NKARI, a town of Asia Minor, in the pashalic of Anatolia, 65 miles north-east of Angora, on an affluent of the Kizil-Irmak. There are

barracks, and a castle on a neighbouring height. Pop. about 18,000.

KARMA'THIANS (Carmathians), so called from Abu Saïd Al-Jenabi, surnamed Al-Karmata, a Mohammedan sect which sprang up in the 9th c. A.D., under the califate of Al-Motamed, and which, by a combination of extraordinary circumstances, succeeded in establishing itself for a time as a political power which threatened to overturn the califate itself. What we have said of the particular creed and tendencies of the Ismailis, under that heading in the SUPPLEMENT, began first to be fully realised and developed about the middle of the 2d c. of the Hedjrah, through one Abdallah Ibn Maimun, an oculist (kaddah) by profession, and a Persian by birth. It was he first who, aided by favourable circumstances, matured a plan which, for the boldness and genius of conception, and for the energy and vigour with which it was carried out, has not many parallels in history. Nothing less was contemplated than the union of the Arabic conquerors and the many races they had subjected since Mohammed's death, and the enthronement of what afterwards was called 'Pure Reason' as the sole deity to be worshipped. The advanced should be free of all so-called religious fetters, which, as symbols and allegorical actions, should be laid all the heavier on the necks of the less advanced strata of society. The 'Believers' and 'Conquerors' were to be made missionaries for unbelief, and the implements for the destruction of their own empire. Whatever the ultimate plans of Abdallah may have been, there can be no doubt about the astute way in which he set to work for the new faith. With an extraordinary knowledge of the human heart and human weakness, he offered devotion to the believer; liberty, if not licence, to the 'free in spirit'; philosophy to the 'strong-minded'; mystic hopes to the fanatics; miracles to the masses. To the Jews, he offered a Messiah; to the Christians, a Paraclete; to the Moslems, a Mahdi; and to the Persian and Syrian 'pagans,' a philosophical theology. His practical exertions, and their wonderful results, soon attracted the attention of the authorities. Obligated to flee from place to place, he sought refuge successively in Karaj, in Ispahan, in Ahwas, in Basra, finally, in Salamia, in Syria, where he died, leaving his son Ahmed his successor as chief of the sect of the Ismailis. This Ahmed, warned by the fate of his father, proceeded with greater caution, more especially with regard to the name of the Imam or Great Prophet, which he left rather uncertain.

Among the missionaries he sent to Irak, there was one named Husein Ahwazi. In the province of Kufa, this missionary, according to some of the authorities, met a man named Hamdan Karmat, whom he converted to the new faith, and at his death laid his mission upon Karmat's shoulders, whom he had previously initiated into the whole extent of the faith. According to others, however, it was Husein himself, who from some cause received the name of Karamita or Karmat, a word the meaning of which is rather uncertain—indicating, according to some, a man who, having short feet, makes small steps; according to others, a man who has red eyes, &c.

Whoever Karmat was, he was the fittest man to carry out the original intentions of the founder. He very soon succeeded in gaining the full confidence of his flock, which increased daily, and in making them blind instruments of his will. He introduced, according to some of the authorities, absolute communism, not only of property, but even of wives, among them, and founded one particular colony, consisting of chosen converts, around

his own house in Kufa. This residence of his, called the House of Refuge, became the centre of an immense conspiracy. From this place all the missionaries were sent out, and all the threads of the great movement were directed. Amongst the most noted of those missionaries was one Abu Saïd, who was sent first to Southern Persia, and afterwards to Bahrein, in the Persian Gulf.

The inhabitants of Bahrein, which had formerly been a province of Persia, were partly Jews, partly Persians, who had capitulated with Mohammed, and had been allowed to retain their own creeds. After the Prophet's death, they had at once shaken off the unwelcome yoke, which, however, had again been put upon them by Omar. The interior of the country was inhabited by certain Arabs, highly disaffected against Islam, the innumerable precepts of which they disliked with an intense dislike. No wonder that Abu Saïd made the most marvellous strides in his conversions. In less than two years, he had brought over a great part of the people of Bahrein. In 287 (Hedjrah) the calif sent an army of 10,000 men against Abu Saïd and his followers, but the latter remained victorious, and made the calif's own general prisoner. He now gained undisputed possession of the whole country, part of which he had only conquered as yet, and having destroyed the old capital Hajar, made Lahsa, his own residence, the capital of the country. While the court of Bagdad was threatened with destruction by this newly established power on one side, two chiefs of another Karmathian branch appeared, the one in the neighbourhood of Kufa, the other in Syria. The first was defeated, captured, and tortured to death; the other was more successful. The governor of Damascus, who marched against him, was beaten most ignominiously. This Karmathian triumph, however, though followed by a few others, was of but short duration. A decisive victory (294 Hedjrah), won by the calif's general, Wasif, for ever put an end to this branch of the Karmathians.

Meanwhile, both Karmat and Abu Saïd had become—by what means, is matter of great obscurity—faithless to their own creed. We have no certain dates about the death of Karmat. Abu Saïd was killed, together with some of his principal officers, in the bath in his own castle at Lahsa, in 301 Hedjrah, by one of his eunuchs; and four years later, his son, Abu Tahir, became his successor, and he has left his name indelibly stamped upon the annals of Islam. In 311, he seized the town of Basra. In the next year, he pillaged the caravan which went to Mecca, and ransacked Kufa. In 315, he once more reappeared in Kufa and in Irak, and gained so decided a victory over the calif's troops that Bagdad began to tremble before him. In 317 (930 A.D.), the great and decisive blow against Mohammedanism was struck. When the great caravan of pilgrims for the annual pilgrimage had arrived at Mecca, the news suddenly spread that Abu Tahir, the terror of Islam, had appeared at the head of an army in the holy city itself. All attempts to buy him off failed, and a massacre of the most fearful description ensued. With barbarous irony, he asked the victims what had become of the sacred protection of the place. Every one, they had always been told, was safe and inviolable at Mecca. Why was he allowed thus easily to kill them—the race of donkeys? According to some, for 6 days, to others, for 11 or 17, the massacre lasted. The numbers killed within the precincts of the temple itself are variously given. The holy places were desecrated, irredeemably almost. But not satisfied with this, Abu Tahir laid hands on the supreme Palladium, the black stone itself.

Yet he was apparently mistaken in his calculations. So far from turning the hearts of the faithful from a worship which God did not seem to have defended, the remaining Moslems clung all the more fervently to it. God's decree had certainly permitted all those indignities to be put upon His house, but it was not for them to murmur. The stone gone, they covered the place where it had lain with their kisses. As often as Abu Tahir did not distinctly hinder them by force, the caravans went on their usual annual pilgrimage. In the year 327, the emir of the pilgrimage, Abu Tahir's own personal friend, first succeeded in persuading him to conclude a treaty by which the pilgrimage was allowed again, on payment of five denars for every camel, and seven for every horse. Yet the black stone, notwithstanding all efforts on the part of the court of Bagdad, was not returned. Abu Tahir seems altogether to have been a man of extraordinary abilities. Of his valour, with which he also knew how to imbue his followers, the following is told. When he had taken away the black stone, and desecrated the holy places, he marched, with 500 horse, upon Bagdad. The Calif Moktader sent 30,000 men, under his best general, to meet him. Having ascertained how small were the rebel's resources, the calif sent a friendly message to him by the general himself, adjuring him, by their previous friendship, to desist from his insane attempt, and to make good his escape in time. Whereupon he asked the messenger of how many the calif's forces consisted. 'Thirty thousand,' was the answer. 'Then go,' he said, 'and tell your master that he has just sent three men too little.' And calling for three of his own men, he commanded one of them to stab himself, the second to throw himself into the Tigris, and the third to jump over a precipice; all of which was instantly done. 'You see,' he continued, 'what my warriors are like, and what numbers mean against such as these.' The following night, he made a sudden attack upon the enemy, routed them completely, and took the general himself prisoner.

Regarding the special form of belief of the K., as far as it has been preserved to us, it seems in the beginning—before Ismaëlism became that mixture of 'naturalism,' 'materialism,' of whilom Sabæism, and of Indian incarnations and transmigrations of later days—to have only been a kind of 'reformed' Islam. The prophet Karmat, it was held, had brought a new Law into the world. By this, many of the Mohammedan tenets are altered, many ancient ceremonies are abrogated, new forms of prayer are introduced, and an entirely new kind of fast is inculcated. Wine is permitted, as well as a few other things prohibited by the Koran. Certain other of the precepts met in this book are turned into mere allegories. Instead of tithes, they gave the fifth part of their property to the Imam. Prayer is but the symbol of obedience to their Imam. Fasting is the symbol of silence, or rather of concealment of the religious doctrine from the stranger.

Abu Tahir died almost absolute master of Arabia, Syria, and Irak, in 332 Hedjrah. It was not until seven years later (950 A.D.), under the reign of two of his brothers who had succeeded him, that the 'black stone' was returned to Mecca for an enormous ransom, and fixed there, on the seventh pillar of the mosque called Rahmat (God's mercy), in the presence of the emir of the mosque and others, a Spaniard amongst them. Yet the K. were accused of not having returned the stone itself, or, at all events, of having broken it. Forty camels, it was also said, had been unable to carry it away; while a single one had brought it back, one, moreover,

that had been lean when it started, and had become fat when it had reached Mecca.

From that time forth, however, the star of the K. began to wane. Little is heard of them of any import till 375, when they were defeated before Kufa—an event which seems to have put an end to their dominion in Irak and Syria. In 378, they were further defeated in battle by Asfar, and their chief lost his life. They retreated to Lahsa, where they fortified themselves; whereupon Asfar marched to Elkatif, took it, and carried away all the baggage, slaves, and animals of the K. of that town, and retired to Basra. This seems to have finally ruined the already weak band of that once formidable power, and nothing further is heard of them in history, although they retained Lahsa down to 430, and later still. Even to this day there exist, according to Palgrave, some disaffected remnants of them at Hasa (the modern name of their whilom centre and stronghold), and other tracts of the peninsula; and their antagonism against Mohammedanism, which they have utterly abrogated among themselves, so far from being abated, bids fair to break out anew into open rebellion at the first opportunity.—See Weil, *Gesch. d. Chalifen*; De Goeje, *Mémoire sur les Carmathes*, &c.; Silvestre de Sacy, *Religion des Druses*; Sale, *Koran*; Palgrave, *Arabia*, &c.

KARR, JEAN ALPHONSE, a French literary man of considerable eminence, was born at Paris on the 24th of November 1808. After getting his preliminary education at home from his father, who was a distinguished pianist, he passed with much distinction through the curriculum of the College Bourbon, in which he afterwards, while very young, became a teacher. While employed in this institution, he fell in love, and began to cultivate the muses; and a copy of verses which he sent to the satirical journal, the *Figaro*, formed his introduction to the literary career. His verses were not accepted by the *Figaro*, but its editor asked him to send something in prose, and the result was that he became a regular contributor to the journal. Disappointed in his attachment, he revealed to the world the story of his grief in a novel entitled *Sous les Tilleuls* (1832, 2 vols. 8vo). A youthful desire to astonish, a determination to seem original, made many ignore the real originality of this work; and the curious blending of irony and sentiment, of good sense and nonsense, which form the author's manner, was puzzling to simple people; but the critics declared the book charming; and the public, to whom youthful traits in a novel are never unpleasing, on the whole concurred in the verdict. Encouraged by the success he had met with, K. soon produced a second novel, which did not diminish his reputation (*Une Heure trop Tard*, 1833); and thereafter, year after year, he produced new works, until he has become a prolific author, and a recognised popular favourite. *Fa Dièze* appeared in 1834; *Vendredi Soir* in 1835; *Le Chemin plus Court* in 1836, the last a work in which he again rehearsed the experiences of his youth—at least, it is popularly believed that in it he told the world his own story. He has since published *Eimerley* (1838); *Genevieve* (1838, 2 vols.); *Clotilde* (1839); *Hortense* (1842); *Am Rauchen* (1842); *Pour ne pas être Treize* and *De Midi à quatorze Heures* (1842); *Feu Bressier* (1845, 2 vols.), originally published in the *Revue des Deux Mondes*; *Voyage autour de mon Jardin* (1845, 2 vols.); *La Famille Alain* (1848, 3 vols.); *Histoire de Rose et de Jean Duchemin* (1849); *Les Fées de la Mer* (1850); *Clovis Gosselin* (1851); *Contes et Nouvelles* (1852). *Agathe et Cecile*; *Fort en Thème*; *Soirées de Sainte-Adresse*; *Les Femmes*; *Raoul*; *Lettres écrites de mon Jardin*; *Au Bord de la Mer*,

appeared between 1852 and 1855; *Promenades hors de mon Jardin* was published in 1857; *La Penelope Normande* in 1858; *La Pêche en Eau douce et en Eau salée*, and the *Dictionnaire du Pêcheur*, in 1860. The publication of a complete edition of his works commenced in 1860. The letters and sketches which he has from time to time written from Nice, his place of residence in later years—upon horticulture, and flowers, and fishes—the pleasures of the country and the seaside—have been among the most delightful and popular of his works.

In 1839, M. K. became chief editor of the *Figaro*, and in the same year he founded a monthly satirical journal called *Les Guêpes*, which he long conducted with the most brilliant success, gaining for himself a very high reputation as a wit and satirist, but making, as was natural, many enemies, of whom one, a lady, made an attempt upon his life, which happily proved abortive. Several volumes of *Les Guêpes* have been reprinted; so also have been three volumes of sketches, which, under the title of *Bourdonnements*, he began to contribute to the *Sicéle* in 1852. M. K. has contributed very largely to periodicals, from which, indeed, many of his works have been republished. At Nice, where he has lived for many years past, he has occupied himself—combining the man of business with the enthusiast—with the growth of flowers and fruits; and the most beautiful bouquets sold in Paris are made up of the produce of his garden. Several new varieties of flowers, especially a dahlia, bear his name.

KARSHI (anc. *Naksheh*), the second city in size and commercial importance of the khanat of Bokhara, Central Asia, is situated on the Shehri Sebz river, 90 miles south-east of Bokhara city. K. is surrounded by cultivated land and numerous gardens. It consists of the city proper and a weakly fortified citadel, has ten caravanserais and a well-supplied bazaar, and is considered likely to be of great importance in the transit-trade organised between Bokhara, Cabul, and India. K. is distinguished for the fabrication of knives of various kinds, which are exported to all parts of Central Asia, as also to Persia, Arabia, and Turkey, where they realise three or four times the cost price. According to Vámbéry, one kind, with Damascus blades, and handles with gold and silver inlaid, are worked with great taste, and might, both for durability and temper, put to shame the most famous produce of Sheffield and Birmingham. The inhabitants, estimated (1863) at 25,000, are for the most part Usbeks, with a mixture of Tadjiks, Indians, Afghans, and Jews; they are distinguished by their cheerfulness and light-heartedness. The Jews have the privilege of riding even in the interior of the city, which they are not allowed to do in any other part of Bokhara.—See Vámbéry's *Travels in Central Asia* (1864).

KASANLIK, or **KEZANLIK**, a town of European Turkey, at the base of the Balkan Mountains, 85 miles north-west of Adrianople, on the Tundja, an affluent of the Maritza. It has an extensive manufacture of attar of roses. Pop. 10,000.

KASHIN, a town of Russia, in the government of Tver, and 80 miles east of Tver, on the Kashinka, a tributary of the Volga. Great part of the town is old and ill built, but it is a place of much activity, rapidly increasing in prosperity and population. Tanning is a principal branch of trade. A kind of paint for the toilet is also largely manufactured. K. is celebrated for the extraordinary number of its churches and other ecclesiastical buildings. Pop. (1863) 7639.

KATUNGA, or **EYEO**, a town of Gando, West

Africa, 25 miles from the mouth of a tributary of the Niger, and about 200 miles north-east of Abomey. It is surrounded by a mud wall and a ditch. There is a brisk trade in yams, corn, goats, sheep, fowls, native cloth, &c. Pop. supposed to be about 15,000.

KEBLE, JOHN, son of the Rev. John Keble of Coln St Alwynds, Gloucestershire, and Sarah Maule, a lady of Scotch descent, was born at Fairford, three miles from his father's living, April 25, 1792. The elder Keble, a divine of the school of Ken, educated his son at home, and with such success, that at the early age of 15, he was elected scholar of Corpus Christi, Oxford, then a small college composed wholly of members on the foundation, but numbering among its scholars such names as Cole-ridge (Sir J. T.) and Arnold of Rugby. In 1810, K. took a first class in Classics and Mathematics; and in the next year was elected to a fellowship at Oriel, one of the highest honours in the university. In 1812, he gained both the Latin and English prize essays, was ordained deacon in 1815, and priest in 1816. Even then, he had chosen his career. Neither the prospect of emolument at Oxford, nor the intellectual attractions of the Oriel common-room, of which Whately and Copleston were then members, and to which Arnold, Pusey, and Newman were soon afterwards added, could charm him from his first love, the life of an English parish priest. For a while he remained at Oxford as tutor and examiner, but soon took active clerical duty, principally assisting his father. In June 1827, in deference to the wishes of his friends, he published *The Christian Year, or Thoughts in Verse for the Sundays and Holydays throughout the Year*, portions of which had been written as early as 1819. The success of the small volume, and its influence on religious thought in England, can hardly be over-rated. The number of editions sold (some of 3000 copies) is marvellous. Although of unequal merit, many of the pieces being evidently written to complete the original plan, it is a work of genuine inspiration, combining with rare depth and fulness of religious feeling, the tenderest sensibility, and a poet's appreciation of nature in her more sympathetic and human aspects. In 1831, K. succeeded Milman as Professor of Poetry. His official prelections are ingenious in theory, and composed in elegant Latin prose. But the time had come when he must quit the pleasant paths of poesy for the tumult of theological controversy. It was a period of peril for the English Church. Within, was apathy and want of spiritual life, save only in the extreme Evangelicals, from whose defects of learning and taste Oxford naturally revolted. Without, a reformed parliament had already suppressed three Irish bishoprics, and seemed not unwilling to lay hands upon the church at home. In his sermon on National Apostasy (1833), K. gave the signal for the Tractarian movement—a movement remarkable for the learning and ascetic saintliness of its promoters, and whose principles were deep submission to authority, implicit reverence for Catholic tradition, with firm belief in the divine prerogatives of the priesthood, the real nature of the Sacraments, and the danger of independent speculation. Early in 1835, old Mr Keble died, and at the close of the same year the poet married Miss Charlotte Clark, the daughter of an old friend of his father, and quitted Fairford for Hursley, a living in the gift of Sir W. Heathcote, M.P. When Newman seceded to Rome, K., less logical perhaps, but with a truer instinct of fidelity to the Anglican Church, remained firm, and amidst the general dismay, exerted himself to the utmost to confirm those who wavered. From this period till his death, his

influence, though comparatively unseen, was not less felt. When smarting under adverse decisions of courts, and hostile measures in parliament, his party always sought for K.'s opinion, and it was given with a conscientiousness that spared no pains, and a singular clearness of judgment even in matters not strictly clerical. His second volume of poems, *The Lyra Innocentium*, was published in 1846, in aid of the fund for rebuilding Hursley Church. Its popularity has never equalled that of *The Christian Year*, to which, indeed, it is inferior both in poetical merit and in catholicity of tone. In the winter of 1865, the health both of husband and wife was seriously impaired. They were compelled to winter at Bournemouth, and there, in the ensuing spring, they died; K. on the 29th of March, at the age of 74; his wife a few weeks later. Besides his poems, K. was the author of a *Life of Wilson*, Bishop of Sodor and Man; an edition of Hooker, usually considered the standard; and several lesser contributions to periodical literature, among others, a *Review of the Life of Scott*, rather famous in its day, originally published in the *British Critic*.

KEITH, JAMES, best known as MARSHAL KEITH, second son of William, ninth Earl Marischal of Scotland, and Lady Mary Drummond, daughter of the Earl of Perth, was born at the castle of Inverugie, in Aberdeenshire, on the 14th of June 1696. He and his elder brother, George, Earl Marischal, had for their preceptor their kinsman, Robert Keith, afterwards a bishop in the Scottish Episcopal Church, and author of two valuable historical works. The brothers took part, on the side of the House of Stewart, in the insurrection of 1715, and after its suppression, were attainted (see KEITH, THE FAMILY OF). Having effected his escape, K. remained in France for some years, improving his knowledge of the military profession, and waiting for an opportunity of obtaining service. In 1719, along with his brother and other Scottish noblemen, he sailed on board the fleet which was fitted out by Cardinal Alberoni and the Spanish court for the invasion of Scotland. The Jacobites were defeated at Glenshiel by the royal army, under General Wightman, and obliged to retreat. The Spanish auxiliaries were ready to renew the battle, but the Highlanders dispersed, and K., after lurking for some time among the mountains, got across the country to Peterhead, and again escaped to the continent. He continued in the Spanish service, but all his expectations of promotion were disappointed, in consequence of his firm attachment to the Protestant Episcopal Church. In 1727, he made an application for the colonelcy of an Irish regiment, and received, as he himself tells us, the following answer from the king of Spain, 'that how soon he knew I was Roman Catholic, I should not only have what I asked, but that he would take care of my fortune.' In consequence of this, he applied for a recommendation to the Russian government, which was immediately given, and he received from the Czar Peter II. a commission as major-general. He distinguished himself in the wars with the Turks and Swedes, particularly at the siege of Oczakoff, and the reduction of the islands of Aland; but finding the Russian service in various respects disagreeable, he entered that of Prussia in 1747. King Frederick knew his merits, and gave him the rank of field-marshal. From this time his name is associated with that of the king of Prussia, who relied as much on the military genius of K., as he did on the diplomatic ability of his brother the Earl Marischal. K.'s talents became still more conspicuous upon the breaking out of the Seven Years' War. He shared the doubtful fortunes of the king before Prague, and was present at the

great victory of Rossbach, and at the retreat from Olmütz. His last battle was not far distant. The Austrians under Daun, and the Prussians under their king, met at Hochkirchen on the 14th of October 1758, K. commanding the right wing. The Prussian army was beaten, and K., surrounded and overwhelmed by numbers, while endeavouring to force his way at the bayonet-point, was shot through the heart. His body was recognised by Count Lacy, formerly his own scholar in the art of war, and was buried at Hochkirchen. The rest may be given in the words of Frederick's historian: 'Four months after, by royal order, Keith's body was conveyed to Berlin; reinterred in Berlin, in a still more solemn public manner, with all the honours, all the regrets; and Keith sleeps now in the Garrison-Kirche—far from bonny Inverugie; the hoarse sea-winds and caverns of Dunnotar singing vague requiem to his honourable line and him, in the imaginations of some few. . . . In Hochkirchen Church there is still, not in the churchyard, as formerly, a fine, modestly impressive monument to Keith; modest urn of black marble on a pedestal of gray—and, in gold letters, an inscription not easily surpassable in the lapidary way: . . . "Dum in prælio, non procul hinc, inclinatam sturum aciem, mente, manu, voce, et exemplo restituēbat, pugnant ut herosas decet occubuit." K. wrote a brief but interesting fragment of a memoir of his own life, commencing with the year 1714, and ending in 1734, which was printed in 1843 by the Spalding Club. For his military career after entering the Prussian service, reference may be made to Mr Carlyle's *History of Frederick the Great*.

KE'MPEN, the name of two towns in Prussia.—1. A town in Prussian Poland in the government of Posen, on the border of Silesia, 43 miles east-north-east of Breslau. It has two churches, a beautiful synagogue, and a hospital. Wax-refining, tanning, and brewing are carried on, and there is a trade in horses. Pop. (1864) 5917, more than half of whom are Jews.—2. A town of Rhenish Prussia, in the government of Düsseldorf, and 20 miles north-west of the town of Düsseldorf, near the Niers. There are manufactures of silk and woollen goods, of articles of wood, stockings, and candles. It is said to be the birthplace of Thomas A' Kempis (q. v.). Pop. (1864) 4714.

KENT'S CAVERN, or KENT'S HOLE, a celebrated bone-cave, situated in a small, wooded, limestone hill, at the junction of two valleys, about a mile eastward from Torquay harbour, and half a mile from the northern shore of Torbay. It consists of two parallel series of chambers and galleries, having an approximately north and south direction. The aggregate length of the eastern series is upwards of 250 feet, and the western is probably longer. It has two narrow external openings or entrances, in the face of one and the same low natural cliff, on the eastern side of the hill, and both opening into the eastern suite of apartments. They are nearly on the same level, about 50 feet apart, 70 feet above the bottom of the valley immediately beneath, and from 180 to 190 feet above the level of mean tide.

Nothing is known respecting the origin of its name, and tradition fails to reach back to the date of the discovery of the cavern. The earliest known mention of it is by Polwhele, who, in his *History of Devon* (1793), gives a minute description of it. At that time, it appears to have been much visited by the curious; but it did not attract the attention of scientific inquirers until September 1824, when Mr Northmore visited it with the 'double object of discovering organic remains, and of ascertaining the existence of a temple of Mithras.' He declared

KENT'S CAVERN.

himself 'happy to say that he was successful in both objects.'

In 1825, the Rev. J. M'Enery commenced those researches, which extended at intervals over fully four years, and has for ever associated his name with the cavern. He made arrangements for the publication of an illustrated narrative of his labours; but the intention was unfortunately abandoned. After his decease, it was feared that his MSS. had been lost or destroyed; but after a variety of fortune, they ultimately fell into the hands of Mr Vivian of Torquay, who, in 1859, edited and published them under the name of *Cavern Researches*.

Mr M'Enery's labours may be thus summed up: (1) In the cave-earth, beneath a thick floor of stalagmite, he discovered remains of the following animals, of which those whose names are printed in italics are extinct: great horse-shoe bat, shrew, badger, polecat, stoat, wolf, fox, wild cat, water-vole, field-vole, bank-vole, Norway hare, rabbit, red-deer, *Ursus priscus*, *U. spelæus*, *Hyæna spelæa*, *Felis spelæa*, *Machairodus latidens*, *Lagomys spelæa*, *Elephas primigenius*, *Rhinoceros tichorhinus*, *Equus fossilis*, *Hippopotamus major*, *Megaceros hibernicus*, and *Strongyloceros spelæus*. (2) Mixed up with those remains, and under precisely the same conditions, he met with a considerable number of flint 'implements,' which had been formed by man.

Though the inoculation of human industrial remains with the bones of extinct mammals was confirmed by the subsequent researches of Mr Godwin-Austen in the same cavern, and later still by those of the Torquay Natural History Society, even scientific men were unprepared for it, and it was either discredited or explained away. In 1858, however, a virgin cavern was discovered at Brixham, on the opposite side of Torbay, and was systematically and carefully explored by a committee, under the auspices of the Royal and Geological Societies of London. The results obtained were so perfectly trustworthy, and so strictly confirmatory of the statements which, from time to time, had been reported from Kent's Hole, that it began to be generally suspected that the latter were, after all, worthy of credence.

As a result of this feeling, the British Association, in 1864, appointed a committee—consisting of Sir C. Lyell, Sir J. Lubbock, Mr Evans, Mr Pengelly, Professor Phillips, and Mr Vivian—to make a complete and systematic exploration of so much of Kent's Cavern as still remained intact. The committee, to which Mr Busk was added in 1866, have carried on their researches without intermission, and presented full Reports in 1865, 1866, and 1867. The work is placed under the superintendence of two of the members, who visit the cavern daily. The method of exploration is so simple as to be easily carried on by the workmen, and so accurate as to render it easy to determine the exact position in which every object was found.

The walls of the cavern, in some of its branches, display traces of the long-continued action of water running in a sensibly horizontal direction. These however, may be regarded as indications of the agency by which the cave was formed, but not necessarily by which the deposits were introduced.

In descending order, these deposits were: (1) Huge blocks of limestone, which from time to time had fallen from the roof. In some instances, two or more blocks lay one on another. Sheets of stalagmite sometimes lay between them, or invested the whole, so as to form a dome-shaped mass; whilst others were without any trace of this material. (2) Black mould, from 3 to 12 inches

deep. (3) Stalagmitic floor, from 3 inches to as many feet thick; but commonly ranging from 16 to 20 inches. With very few exceptions, it extended to the walls quite across every chamber and gallery. In some cases, it was crystalline, compact, and so very hard as almost to defy the workmen's skill and best tools; in others, it was earthy, granular, and comparatively soft. It commonly consisted of thin laminae, alternately crystalline and granular. It contained numerous fragments and blocks of limestone, and graduated downwards into an extremely hard concrete or breccia. (4) A black band, of irregular outline, from 2 to 6 inches thick, containing numerous bits of charcoal, and strongly resembling the black mould above the stalagmite. This band was exceptional, being found only in one spot, from 30 to 40 feet from one of the cavern entrances, where it covered about 100 square feet only. Throughout about half this area, it was in immediate contact with the nether surface of the stalagmitic floor, from which, elsewhere, it was separated by a layer of red loam, which never exceeded 6 inches in thickness. (5) Red cave-earth, with angular fragments of limestone, from mere splinters to blocks almost as large as those lying on the surface. Typically, this deposit consists of about equal parts of red earth and of stones; but in some places, the former greatly preponderates; whilst in others, the latter is most prevalent. Comparatively small well-rounded fragments of rocks, not derivable from the cavern hill, occasionally present themselves. The materials of the cave-earth have no approach to stratification or symmetrical arrangement, and the stones lie at all angles. Small thin films of stalagmite occur at all depths, sometimes encrusting bones or stones, or cementing them into a firm breccia. The depth of this deposit is unknown; for, at present, it has been found desirable to limit the excavation to a depth of 4 feet below the base of the stalagmitic floor.

The objects found in the black mould, above the stalagmite, form a large and very miscellaneous collection, including objects extending from the present day back to mediæval, and even pre-Roman times. The most important are stones of various kinds, well rounded, and occasionally perforated by marine organisms; potsherds, representing a large number of vessels; curvilinear plates of slate, probably covers for earthenware utensils; 'spindle whorls'; amber beads; an awl, a spoon, a wedge, and a chisel, all formed of bone; bone combs, which may be likened to small shoe-lifters having teeth in the broad end; a spear-head, a socketed celt, a spoon, a fibula, and rings, all in bronze; lumps of smelted copper; marine shells, such as still exist in Torbay; and bones and teeth of various animals, of existing species, including man.

The comparatively few objects found in the stalagmitic floor include pebbles of various kinds, flint implements, marine shells, pieces of charcoal, and remains of extinct and recent animals, including man, and the cave rhinoceros, hyæna, and bear.

The black band beneath the floor was extremely rich in objects, of which the principal were remains of the ordinary extinct and recent cave mammals; flint implements and chips; a bone awl; a bone fish-spear, or 'harpoon,' barbed on one side only. The flint specimens were keen-edged, brittle, and chalk-like in colour and texture. They averaged about ten in every cubic foot of material.

Throughout the entire depth yet excavated, the red cave-earth contained bones of recent and extinct mammals and birds—chiefly the former; fecal matter, almost exclusively finely comminuted bone; *ovate* and *lanceolate* flint implements, and flint

chips; a bone 'harpoon'; a bone pin; small pieces of burned bone; 'whetstones,' and a stone hammer, or crusher. The bones are very abundant: most of them are of an almost chalk-like whiteness, whilst a few are discoloured; many are merely small splinters; a considerable number have been fractured, and gnawed precisely after the manner of modern hyenas; several are split longitudinally, as if for the extraction of the marrow, and in such a way as to betoken human agency; most of those thus split have also been scored by hyenas's teeth; those immediately under heavy blocks of limestone are crushed; they are all characterised by a specific gravity greater than that of those found above the stalagmite; on the tongue being applied to them, they all adhere to it; in no instance have the elements of an entire skeleton, or anything approaching to it, been found together; and remains of many different kinds of animals are often lying in contact. Certain branches of the cavern appear to be richer than others in bones; but wherever the cave-earth occurs, with its usual accompaniment of limestone fragments, they may be expected in average abundance, irrespective of depth below the stalagmite. The faecal matter appears to be confined to certain branches of the cavern, where it occasionally occurs in heaps a foot high. The bone 'harpoon' and pin have the same chemical condition as the bones—they both adhere firmly to the tongue. The former was found 2 feet below the stalagmite, and the latter 4—the greatest depth yet excavated. The best ovate flint tool was also met with at this depth. The 'whetstones' are long narrow pieces of greenish grit, not such as could be supplied by the immediate district, but which might have been obtained from the gravel of the neighbouring rivers—the Dart and Teign. Whetstones similar in form and material have been found in the Bruniquel caves in France. The 'stone hammer' is a small ellipsoidal pebble of coarse, hard, red sandstone. Such pebbles occur plentifully on the central shore of Torbay. Hammers of this kind are well known to have been used by the North American Indians.

It may be doubted whether the investigation now in progress has made any additions to the list of cave mammals given by the early explorers; indeed, up to the present time, no traces have been found of *Machairodus latidens*, recorded by M'Enery, or of *Hippopotamus major*, placed by Professor Owen in the cavern list. Though some degree of scepticism exists in certain minds respecting their occurrence in the cavern, the evidence is such as to justify the belief that machairodus, at least, may yet be exhumed. In fact, the researches now carried on are continually adding new confirmations of M'Enery's statements, and hitherto they have failed to bring forth any conflicting evidence.

Though it would be premature to venture on a general interpretation of the facts disclosed before the exploration is completed, the meaning of a few of them cannot be misunderstood or qualified.

From the crushed character of the bones immediately beneath blocks of limestone, it may be inferred that the cave-earth, on which they lay, was firm, unyielding, and capable of offering a resistance to the huge blocks as they fell from the roof; and hence it may be concluded, also, that the flint-tools did not, as Mantell and others supposed, by sinking through the red earth, reach a depth greater than that which they primarily occupied.

Whilst it is possible that objects belonging to different eras may be commingled in the cave-earth, it is certain that the most modern thing it contains is more ancient than the oldest article in the

stalagmite formed on it; and as human tools have been found in the red earth, and bones of three extinct mammals in the stalagmite, the contemporaneity of man with these extinct forms may be regarded as certainly established.

It is no doubt true that a very large amount of labour has been expended on Kent's Cavern without the discovery of any portion of the human skeleton in the cave-earth. The fact is one of considerable interest, but it does not warrant a doubt respecting man's existence, especially in the presence of such positive facts as bone-tools and burned bones, to say nothing of the flint implements. Moreover, the stalagmite floor, with its extinct mammals, has yielded a portion of man's osseous system—part of an upper jaw, containing four teeth. In their Reports, the exploring committee remark, that, amongst other results of their investigation, so many instances of the valuelessness of merely negative evidence have presented themselves, as to encourage the hope that remains of man, though probably in but sparing numbers, may yet be found in the cave-earth.

KERKI, a town of Bokhara, Central Asia, about 120 miles south of Bokhara city, on the left bank of the Jihoon or Oxus. K. is a place of considerable importance, being a frontier fortress, and the key to Bokhara on the side of Herat. The town, which is spread around the fortress, consists of 150 houses, 3 mosques, a small bazaar, and a caravanserai; it is also defended by a good wall and deep ditch. The inhabitants are Uzbeks and Turkomans, employed a little in trade, but more in agriculture.—Vámbéry's *Travels in Central Asia*.

KERN, J. CONRAD, a Swiss statesman, was born in 1808, in the neighbourhood of Arenenberg, in Thurgau. He received his elementary education at Zürich, and afterwards studied theology at Bâle; but he abandoned his intention of entering the church, and turned his attention to law, which he studied successively at Berlin, Heidelberg, and Paris. On his return to his native canton, he was appointed to the presidency of the Supreme Court and of the Council of Public Instruction; and in these offices he made himself remarkable by his talent for public speaking, and the excellent suggestions which his wide acquaintance with other legal and administrative systems enabled him to make for the amendment of the institutions of the canton. K. was member of the Swiss diet for Thurgau in 1837, when Louis Napoleon came to reside at Arenenberg. His mother had settled there, and he had acquired the rights of a citizen of the canton. The government of Louis Philippe demanded his extradition, but the Swiss refused to compel him to leave the territory of the republic. They were threatened with invasion; and a spirited discussion took place in the diet, in which K. took the most prominent part, and stirred up his countrymen against the demands of the French. The canton entirely supported what he had done; but, fortunately, any resort to hostilities was rendered unnecessary by the voluntary retirement of Louis Napoleon. In 1848, K. took an active part in the preparation of the federal constitution, and some of its best features are due to his sagacity. He afterwards established the Polytechnic School of Zürich, one of the most admirable institutions of its kind in Europe. While director of this school, in 1857, he was selected, in consequence of his early connection with Louis Napoleon, to complete the negotiations regarding the dispute with Prussia; and at the conferences of Paris between the great powers, K. represented Switzerland. It is understood that K.'s influence with the emperor induced

the latter to espouse very warmly the cause of the republic, and to secure the consent of the king of Prussia to the treaty by which he renounced his sovereign rights over Neuchâtel, and the voluntary abandonment, on the part of Prussia, of the indemnity of a million francs, which the Swiss had stipulated to pay.

KEY ISLANDS lie to the south of New Guinea, between 5° 12'—6° 4' S. lat., and 132° 40'—133° 18' E. long. They consist of Great Key, Little Key, Key Watela, and a number of small islands. In 1853, two new islets appeared in connection with earthquakes which occurred on the 26th of November.—Great Key is long and narrow, tapering to a point in the south. North-east Cape is in 5° 14' S. lat., and 133° 19' E. long. It is mountainous, and watered by several rivers. The coast is covered with forests. Area, 294 sq. miles. Many of the inhabitants are Mohammedans, some Christians, and the remainder heathen. Pop. 21,000.—Little Key lies south-west from Great Key, in 5° 31' S. lat., and 132° 55' E. long. Area, 283 sq. miles. The shore is low and sandy; the interior more elevated and well wooded. The island is surrounded by reefs, which yield much *bêche-de-mer* and tortoise-shell. It is rich in birds of paradise. Dulah and Tuallah, on the north-west, have safe roadsteads for large ships at all seasons. Good vessels are built at Dulah. Pop. of Little Key, 10,000.—The Key Islands are fertile, and produce fine timber-trees. Goats and pigs are abundant. Oil, cocoa-nuts, wood-work, *bêche-de-mer*, tortoise-shell, &c., are exchanged, to traders from Macassar, for rice, sago, tobacco, sugar, gambir, hatchets, knives, ironwork, elephants' tusks, beads, guns, and articles of clothing. The inhabitants are industrious and enterprising, peaceable, faithful, and honest; of a brownish complexion, moderate stature, well made, with high forehead and regular features. Their hair is black and curly, but not woolly. Sago and fruits are principal articles of food. The villages are mostly built on heights, and surrounded with stone walls.

KHAFALOU'N, or **KHAPALU**, a town of Western or Little Tibet, in the territory of Gholab Singh, on the Shayook, a short distance above its junction with the Indus, 110 miles north-east of Serinagur. Pop. 12,000.

KHANPU'R, a flourishing commercial town of North-western Hindustan, on a canal which connects it with the Indus, 400 miles west of Delhi, in lat. 28° 35' N., long. 70° 41' E. The surrounding country is populous, and where irrigated, fertile. The town is badly built, and most of the houses are of clay. There is, however, a good bazaar, and a fine mosque. It was formerly of much greater importance than it is now, although it still has considerable trade. Pop. 20,000.

KHO'I, a town of Northern Persia, province of Azerbaijan, on the Kotonra, a feeder of the Araxes, 50 miles north-west of Tabriz, and about 20 miles north of Lake Urumeyah. The town is well fortified, and its principal streets are wide and regular, and shaded with avenues of trees. It has a handsome caravanserai, several mosques, and a good bazaar. It has a considerable trade. In the neighbourhood, Shah Ishmael totally defeated the Turks under Selim I., in 1514. Pop. 30,000.

KHU'RJA, a town of British India, in the district of Boolundshuhur, the principal place of the pergunnah of the same name, 54 miles south of Meerut, about two miles west of the Ganges Canal. Pop. 22,147.

KIKI'NDA, **NAGY-KIKINDA**, or **GROSS-KIKINDA**, a town of the Austrian Empire, in the

Temeser Banat, 134 miles south-east from Pesth. It is situated in a level fertile country. The inhabitants are partly of the Greek and partly of the Roman Catholic church. There is some trade in cattle, and an important annual fair. The railway from Pesth to Temeswar passes close to the town. Pop. 17,462.

KI'MPOLUNG, a town of Walachia, 80 miles north-west from Bucharest, on a feeder of the Arjish, near a pass through the Carpathian Mountains into Transylvania. It covers a large surface, has several Roman Catholic and Greek churches and convents, and a considerable trade. Pop. 1860) 8283.

KINCHOW', a city of China, in the province of Hoo-pee, on the left bank of the Yang-tze-Kiang, in lat. 30° 28' 40" N., long. 112° 8' E., about 150 miles west of Hankow. K. is surrounded by a strong wall, and is considered one of the keys of the empire. Pop. estimated at 600,000.

KING-TE-CH'ING, a town of China, in the province of Kiang-si, 240 miles south-west of Hangchow, on a small river which falls into Lake Poyang. It is the principal seat of the manufacture of porcelain in China, for which, it is said, 500 furnaces are employed. Pop. estimated at 1,000,000.

KING-WOOD, a very beautiful wood, in small pieces, used for ornamental work. It is brought from Brazil, and is believed to be the wood of a species of *Triptolomia* (natural order *Leguminosæ*, sub-order *Papilionaceæ*).

KIRCHHEIM, a town of Württemberg, and capital of a bailiwick of the same name, in the Circle of the Danube, is situated in a delightful and fertile district, at the junction of the Lauter and the Linbach, 15 miles south-east from Stuttgart, and forms the central point of several public roads. On a height is seen the old castle of the Teck family, who formerly owned the town. The chief buildings are the royal palace and the Church of St Martin. There are many orchards and vineyards. The principal industries are the manufacture of cotton and linen fabrics, bleaching, making musical instruments, &c. Pop. (1864) 5548, nearly all Protestants.

KIRK-KILI'SSIA (the 'forty churches'), a large but ruinous and miserable town of European Turkey, in Rumili, 104 miles north-west of Constantinople. The town is situated on a sloping ground near the base of the Balkan, is enclosed by walls, and has many mosques and baths. It is famous for the manufacture of a sweetmeat, composed of the inspissated juice of boiled grapes, formed into rolls containing walnut kernels. There is a trade in wine and corn. The pop. is variously estimated at from 16,000 to 28,000, and consists chiefly of a mixed race of Bulgarians, Greeks, and Turks.

KISHENAU', or **KICHENEV**, a town of Russia, capital of the government of Bessarabia, picturesquely situated on the Buik, a tributary of the Dniester, 95 miles north-west of Odessa. Until 1812, when it came into the possession of Russia, it was a small miserable place, of no consequence; since then, however, it has rapidly increased in size and prosperity. It now covers three hills, has 14 churches, a synagogue, gymnasium, several schools, and a government library. It has extensive manufactures of woollen cloth, brandy, leather, candles, &c., and a considerable trade in corn, cattle, flax, hemp, tobacco, fruit, wine, &c. Pop. (1838) 13,000, (1849) 42,636, (1858) 85,547, (1863) 94,124, composed of Russians, Jews, Cossacks, Poles, Germans, Armenians, Bulgarians, Greeks, gipsies, and many other nationalities.

KLEENE' BOC (Dutch, little goat), or **CAPE**

GUEVEI (*Antilope perpusilla* or *pygmaea*, or *Cephalopus pygmaea*), a very small species of antelope, very plentiful in South Africa. It is only about a foot high at the shoulder; the limbs are slender,

Kleene Boe (*Antilope perpusilla*).

the head long and pointed, the horns very short; the colour slaty brown. It lives singly or in pairs, in bushy districts, and is very nimble and active. Similar species are found in Western Africa.

KLIPSPRINGER (Dutch, cliff-springer), or **KAINSI** (*Antilope oreotragus*, or *Oreotragus saltatrix*), a species of antelope, about equal in size to the chamois, and resembling it in habits, found in the highest mountainous districts of South Africa. It is of a yellowish-gray colour, and the hair is long, and stands out from the skin so as to make a rough

Klipspringer (*Antilope oreotragus*).

fur. The legs and the general form are more robust than in most species of antelope. The flesh of the K. is particularly esteemed; the hair is also valued for stuffing saddles; and it has therefore become rare in localities where it was once common. The pinnacles and precipices in which it delights, make hunting it with dogs impossible, but to get within rifle-shot of it is not difficult.

KNEADING BY MACHINERY. Every person who has witnessed the making of bread by the ordinary process, must have felt the necessity of some means for avoiding the contact of hands, often not too clean, with the dough, and the very laborious exertions requisite for kneading it thoroughly. On the continent, where bread-making is treated in a much more scientific way than in Britain, every operation is now conducted on a large scale by the aid of admirable machinery; and the forms of kneading-machines are very various—the general

principle being, however, the same in all. In France, where they are called *Pétrisseurs*, that shewn in the engraving is preferred. It consists of an iron cylinder, in which an axle works, and around which are set a number of curved, blunt metal blades. The upper half of the cylinder opens (as seen in the

Kneading-machine.

figure), for the supply and removal of the dough. In the large bakeries, they are worked by steam-power; in the smaller ones, by hand.

KNOT (*Tringa canutus*), a bird of the family *Scolopacidae*, and of the same genus with the dunlin, stints, &c. It is sometimes called the **RED SAND-PIPER**. Its whole length is about ten inches. The general colour, in summer, is reddish brown, finely mingled with black, gray, and white; in winter, the plumage becomes mostly ash-gray, and on the under parts white. The K. frequents high northern latitudes in summer, and breeds there; but migrates southwards in winter, and is then found, sometimes in large flocks, in Europe, Asia, and America, as far south as the West Indies, chiefly on flat sandy shores. It runs about with

Knot (*Tringa canutus*).

great activity as the wave retires, seeking its food on the sands. Its food consists in great part of small bivalve molluscs, which it swallows shell and all. It is in high esteem for the table.

KO'BRIN, or **KOBRYN**, a town of Russian Poland, in the government of Grodno, 139 miles east from Warsaw, on the right bank of the

Machazica, a tributary of the Northern Bug. It is favourably situated for commerce, the Machazica, and along with it the Bug and Vistula, being here connected by a canal with the Pripet, and thus with the Dnieper. There is a Greek abbey here. Pop. (1863) 8267.

KÖNIGSWARTH, a town of Bohemia, on a feeder of the Beraun, a branch of the Elbe, 79 miles west-south-west from Prague. It is situated in a romantic valley, has a fine castle, belonging to Prince Metternich, mineral springs, and a bathing establishment. The old fortress was destroyed by the Swedes in the Thirty Years' War, and the site having been purchased by the imperial general, Count Metternich, in 1618, he built a castle in the Italian style, surrounded it with a fine park, and collected in it a fine library, with great treasures of paintings, antiquities, and objects of natural history. The altar of the richly-adorned chapel of the castle possesses many bones and other relics of saints to which pilgrimages are made. Pop. 7494.

KORO'TCHA, or **KAROTCHA**, a town of Russia, on a small river of the same name, in the government of Kurak, 75 miles south-east of the town of Kurak. The town is well built, and has several churches. Saltpetre is manufactured, and a trade in apples carried on. Pop. 6392.

KRAPINA, a town of the Austrian Empire, in the province of Croatia, on a river of the same name, a branch of the Save, at the southern base of the Ivanica Mountains, 140 miles south-south-east from Vienna. The surrounding country is very fertile, abounding in corn and wine; and the town has of late rapidly increased in size. Pop. 12,888.

KREMSIR, one of the prettiest towns of Moravia, 88 miles north-east of Olmütz, on the March. It is the summer residence of the Archbishop of Olmütz, who has here a fine palace, containing a picture-gallery and a library of 30,000 volumes. During the revolutionary disturbances at Vienna in 1849, K. was the seat of the Austrian government and imperial councils. Pop. 9110.

KRIS, a dagger or poniard, the universal weapon of the inhabitants of the Malayan Archipelago. It is made of many different forms, short or long,

Kris, or Malay Dagger.

straight or crooked. The hilt and scabbard are often much ornamented. Men of all ranks wear this weapon; and those of high rank, when in full-dress, sometimes carry three or four. In Java, women sometimes wear it.

KRO'NENBERG, a town of Rhenish Prussia, three miles south-east from Elberfeld, in the industrial activity and prosperity of which it has partaken. Manufactures of linen and cotton are carried on, also of articles of iron and steel. Pop. (1864) 7874.

KRUPP'S STEEL. The widespread reputation of the steel produced in the great works of Herr Krupp, at Essen, in Prussia, has induced us to give it a brief notice. His manufactory has been increasing annually from one-sixth to one-third in size for the last 40 years, until it now covers about 450 acres, and gives employment to some 10,000 persons. For large metallurgical works, Essen is favourably situated, being in the centre of a coal-bearing area, where coal of the purest kind can be procured at

from 7s. to 9s. per ton. There is also at hand the manganiferous iron ores of Prussia, which have been found so excellently adapted for the manufacture of steel; but it is believed that the admirable organisation of every part of his manufactory has conducted, as much as anything, to the great success of Krupp. With labourers and mechanics who have passed the regulation-time in the Prussian army, overseers trained in the German technical schools, and a small staff of experienced analytical chemists, he has obviously a great advantage in conducting operations where order, system, and skill are of paramount importance. But even with these benefits, Krupp's productions would not have gained their celebrity, were it not for the scrupulous care with which he performs every manipulation.

In the article *Iron*, we have described the manufacture of steel by the *Cementation* and *Bessemer* processes, but there are several other methods of making it, and one of these is by the decarburisation of cast-iron in the puddling furnace. This is the process by which Krupp makes his steel, in the first instance; and the material he employs is *Spiegelisen*, or specular cast-iron, a highly crystalline variety, usually containing about 4 per cent. of manganese. This iron is admirably suited for conversion into steel. The puddling process for steel is similar to that employed for Iron (q. v.), except that the former is conducted at a lower temperature, and requires nicer management; but in the case of steel, the cast-iron to be operated upon is never previously refined. Cast-iron to the extent of about 4 cwts. is melted in the puddling furnace, mixed with a quantity of slag or cinder (chiefly silicate of iron), and stirred with a rabble. During this operation, the carbon in the cast-iron (usually about 5 per cent.) is gradually oxidised by the oxygen present in the cinder; carbonic oxide is produced, and as it escapes, what is technically termed 'boiling' takes place. When the ebullition becomes active, the temperature is raised until the appearance of incipient solidification occurs; the heat is then lowered, and the ordinary process of baling proceeded with. Steel thus produced usually contains from 0.5 to 1 per cent. of carbon; but if the temperature is not skilfully regulated, the carbon becomes wholly burned away, and malleable iron instead of steel is produced.

Puddled steel, although useful for most purposes in the arts (except cutlery), nevertheless wants homogeneity, on account of a certain intermixture of cinder, which is difficult to get rid of without fusion—a defect which is apt to prevent it from welding perfectly. In Krupp's works, the puddled steel is remelted into crucibles, in order to convert it into cast-steel; and it is the wonderful uniformity of quality with which he manufactures this in very large masses, that constitutes the superiority of, and gives so great an interest to his productions. The crucibles employed are made with extreme care, mainly from fire-clay, to which a little plumbago is added; their capacity varies from 50 to 100 lbs., and it is reported that as many as 100,000 are kept drying at the same time. After being once used, the crucibles are broken up, whether damaged or not, and mixed with other material, to make new ones.

In the casting-house where the large ingots are run, the furnaces, which contain about 1200 crucibles, are arranged along the sides of the building; and in the central portion, the steel moulds, varying in capacity from 100 lbs. to 40 tons, are disposed in line between two pair of rails, upon which runs a movable crane. It is in the casting of such an enormous ingot as 40 tons of steel (the largest yet produced) from crucibles of small capacity,

that the perfect organisation of Krupp's establishment becomes most strikingly apparent. At a given signal, one gang of workmen remove the crucibles from the furnaces, while another seize them with tongs for the purpose, and pour their contents into narrow canals of wrought-iron, lined with fire-clay, which converge into the opening by which the mould is filled. This is the critical stage of the operation, the difficulty being to deposit in the mould a continuous stream of melted steel of about the same degree of heat, so as to cool uniformly, and to solidify into a perfectly homogeneous mass. Of such uniform soundness are some of Krupp's large steel ingots, that one—shewn in the last Exhibition in London, 9 feet high, 44 inches in diameter, and weighing 21 tons—when broken across, did not shew the slightest flaw, even when examined with a lens; and another, weighing 15 tons, although broken at eight different places, shewed an equally perfect structure.

In order to manipulate these extraordinary masses of steel, there is a steam hammer, weighing 50 tons—the mechanical marvel of the works at Essen—which has a cylinder nearly 6 feet in diameter. It has a 50-ton crane at each of its four corners, and behind each of these again, there are four heating furnaces. A movable bench on low massive wheels serves to remove a large ingot from any of the furnaces, which is then, by means of the powerful cranes, and a system of pulleys and crabs, placed on the anvil, and worked into any desired shape. The anvil-face weighs 185 tons.

The quantity of steel manufactured by Herr Krupp in the year 1866 amounted to 61,000 tons, representing a value of about £1,500,000. It consisted chiefly of rails, tires, crank-axes, shafts, mining pump-rods, and guns—the proportion of ordnance being about two-fifths of the whole. Guns have been made at Essen for the Prussians, Austrians, Belgians, Dutch, Italians, Turks, Japanese, and also for the English, although not directly ordered by the government. A brief inventory of the machinery, &c., employed in these works has been published this year, which had it not been issued by the owner himself, would hardly be believed. It states that there are 195 steam-engines, ranging from 2 to 1000 horse-power, 412 furnaces of various kinds, 49 steam-hammers, 110 smith's forges, 318 lathes, 111 planing-machines, 61 cutting and boring machines, 84 boring-machines, 75 grinding-machines, and 26 special tools; 1000 tons of coal are burned daily, and there are about 11,000 gas burners, consuming in the 24 hours of the shortest day 400,000 cubic feet of gas. In the Paris Exhibition of last year (1867), Krupp shewed a huge gun intended for a coast battery to defend the attacks of plated ships. It is made entirely of cast-steel, weighs 50 tons, and can propel a shot weighing 1080 lbs. It took 16 months, working day and night without interruption, to manufacture. The price of the gun alone is £18,750, and of its carriage and turn-table, which weigh respectively 15 and 25 tons, £6000 more. He also exhibits a superb crank-axle for a marine engine, about a foot in diameter, which is a remarkable example of what can now be done in steel, and augurs well for future achievements with this invaluable material.

KRUSENSTERN, ADAM JOHN, CHEVALIER VON, a distinguished Russian voyager, was born 8th November 1770, at Haggud in Esthonia. He served for some time in the British navy. The Emperor Alexander, when he ascended the Russian throne, took up a plan proposed by K. for the promotion of the American fur-trade, and consequently intrusted him with the command of an expedition at once for

scientific and mercantile objects. K. sailed from Cronstadt with two ships, 7th August 1803, and returned 19th August 1806, and was the first to conduct a Russian expedition round the world. He failed in one of the objects for which he was sent out—the reopening of the Russian trade with Japan, but made some interesting geographical discoveries; and his careful explorations of coasts made his voyage very important for the progress of geographical science. He published an account of this voyage (3 vols., Petersb. 1810—1812, with a volume of maps and plates), which was soon translated into all the principal languages of Europe. The contributions to natural history resulting from the expedition were the subject of a separate work by Tilesius (Petersb. and Leip. 1813); and K. himself subsequently published a work called *Contributions to the Hydrography of the Pacific Ocean* (Leip. 1819), and several other works on the same subject. K. died 12th August 1846 at Asz, in Esthonia, where he had an estate.

KRYLOV, IVAN ANDREJEVITCH, a celebrated Russian fabulist, born 13th February 1768, at Moscow, was the son of a poor officer in the army, received the elements of his education at Tver from his mother, and learned French from a French tutor who was resident in the house of the governor of Tver. K. read indiscriminately all books which fell into his hands. Dramatical works made the greatest impression on him, and in his 15th year he wrote an opera called the *Kafetinitsa* (The Coffee Fortune-teller), which was never represented, but attracted considerable notice in Tver, and procured patrons for him, who got him an appointment, in 1785, in a public office in St Petersburg. A bookseller gave him 60 roubles for the manuscript of his opera, which he spent in buying the works of Racine, Molière, and Boileau. In 1786, he wrote another tragedy, *Philomela*, which, although never represented, was printed in the collection called *The Russian Theatre*. After the death of his mother, 1788, to whom he was much attached, K. received a post in the imperial cabinet, which he resigned two years afterwards, in order to devote himself to literary work. For two or three years, beginning in 1789, he occupied himself partly with journalism, but soon gave it up. He now produced a succession of prose comedies, among which were *The Crazy Family* (1793), *The Mocking-bird*, and *The Poet in the Anteroom* (1794), which brought him under the Empress Catharine's notice. In 1801, he was appointed secretary to Galitzin, the governor of Riga, who, after a time, invited him to his country-house at Saratov, where he spent some years in entire leisure. He then returned to St Petersburg in 1806, where he brought several very successful plays on the stage, *The Milliner's Shop*, *The Lesson to Ladies*, &c. It was at this time, when about 40 years of age, that he turned his attention to that kind of writing which was to immortalise him. K. having translated some of Lafontaine's fables, the poet Dmitriev was so struck with their felicity, that he encouraged him to persevere in that line. In 1808, the first collection of his Fables (23 in number) appeared, which met with great success. Others followed in 1811 and in 1816. In 1811, he was made member of the Petersburg Academy; in 1812, an official in the Imperial Library; in 1830, councillor of state; and in course of time he was so overwhelmed with honours and pensions, that, in 1841, when he resigned his public office, he drew from the state and the imperial treasury the sum of 11,700 roubles. On the occasion of his 70th birthday, homage flowed in on him from all quarters. K. died on the 21st November 1844. Soon afterwards, a national

subscription, to which children eagerly contributed their share, was set on foot to raise a monument to his memory; and towards the end of the reign of the Emperor Nicholas, his statue in bronze, by Kloth, was placed in the Summer Garden at St Petersburg. Many stories are current of his eccentricities. Owing to the genuine national spirit, the joyousness, simplicity, wit, and good humour that pervade them, his Fables are the most popular of Russian books, and many single sentences of them have become proverbs. They are generally the first reading-book put in the hands of children, and thus many thousand copies, both in dear and cheap editions, are in circulation among all classes. He produced in all nearly 200 fables, of which more than three-fourths are original, and the rest are imitations. There is a German translation of K.'s Fables by Torney (Mittau, 1842), and there are numerous imitations of them in Italian and in French, the latest by Charles Parfait (Paris, 1867).

KUNNOJ, or **KUNNOUJ**, a decayed town of British India, capital of the pergunnah of the same name, in the district of Furruckabad, 65 miles north-west of Lucknow, on the Kali Nuddi River, about three miles from its junction with the Ganges. At present, the place is little more than an expanse of ruins, whole mountains of which meet the eye in every direction, upon a space of ground much larger, it is said, than the site of London. The greatest part of the standing buildings are uninhabited, and tottering to decay. The few poor people now in

the place live in mud huts built up against the old walls. The present town is about a mile long, and half a mile broad, with a ruinous fort of no great antiquity. The most remarkable buildings are two handsome Mohammedan mausoleums. K. was formerly one of the greatest of Indian cities; and according to some, ranks second in respect of antiquity. One authority considers the town to have existed before the first introduction of Brahmanism from the West. Until about the 12th c. A. D., it continued to be the chief city of India; but in 1194, it was attacked by Shahabuddin Mohammed, sovereign of Ghoor, who defeated the king of K., and overthrew that monarchy. After this, the history of the place consists only of a succession of disasters. At present, this once celebrated place contains only 16,000 inhabitants, living in great indigence.

KUPPERWU'NJ, a fortified town of British India, in the presidency of Bombay, 32 miles east of Ahmedabad, on a tributary of the river Saburmuttee. It has some trade, and manufactures of soap and pottery. Pop. 13,000.

KURNAL, a town of British India, in the district of Paniput, in the North-west Provinces, on the right bank of the Delhi Canal, 78 miles north-east of Delhi city. The town is surrounded by a ruinous wall, and is excessively filthy. It has, however, a handsome mosque. Adjoining the town is a military cantonment. Pop. 20,178.

L

LABEDOYÈRE, CHARLES ANGELOU HUCHET, COUNT DE, a victim of the reaction of 1815 in France, was descended from an ancient family in Bretagne, and was born in Paris on 17th April 1786. He early entered the army; was adjutant to Marshal Lannes in Spain, in 1808, and received a severe wound at Tudela; joined the army in Germany after his recovery; distinguished himself at the capture of Ratisbon, and was Murat's adjutant at the battle of Esslingen. On the evening before the battle of Lützen, Napoleon promoted him to the command of a regiment of infantry. Returning to France again severely wounded, in the autumn of 1813, he married a lady of a family very much attached to the Bourbons; and receiving the command of a regiment, was posted near Vizelle when Napoleon returned from Elba. He immediately joined him, and was made a lieutenant-general and peer of France. He fought with great gallantry at Waterloo; and after the battle hastened to Paris, when he spoke with great violence against the Bourbons in the stormy sitting of the Chamber of Peers, on 22d June 1815. After the capitulation, he thought to have escaped to America, but was taken prisoner, condemned to death, and notwithstanding every effort that could be made on his behalf, shot on 19th August 1815. He was a man of a chivalrous character, and devotedly attached to the emperor.

LABLACHE, LUIGI, a celebrated operatic singer, was born in Naples in 1795, whither his father and mother, who were French, had fled from Paris

during the horrors of the Revolution. His first engagement as a singer was at the San Carlo Theatre at Naples, in 1812; he afterwards sang, with much success, in La Scala, Milan, and in Vienna; singing also at the San Carlo, at Naples, during the intervals of the Vienna season. On his first appearance in London in 1830, he created a great public sensation; and for a number of years, he resided alternately in the French and English capitals, singing both in the Paris and London seasons. He died at Naples in 1858. His voice, a deep bass, has hardly ever been equalled either in volume or quality; and his acting, particularly in the characters of 'Figaro' and 'Leporello,' was almost as remarkable as his singing. He was the author of a treatise on singing, published in 1843; and he long gave instructions in singing to Queen Victoria.

LACROIX, SYLVESTRE-FRANÇOIS, a French mathematician, was born in Paris in 1765; and though of poor parentage, succeeded through indomitable zeal in acquiring so great a knowledge of elementary mathematics, that, at the age of 17, he obtained, by the recommendation of Monge (q. v.), the professorship of mathematics in the Naval School at Rochefort. He was successively promoted to a corresponding position in the Ecole Normale, Ecole Polytechnique, the Sorbonne, and the College of France; was chosen member of the Academy of Sciences in room of Borda in 1799; and throughout his long life zealously pursued his duties as a teacher, widely disseminating a taste for the mathematical sciences by the numerous elementary works which were the fruit of his leisure hours. L. is not remarkable for original discovery in mathematical science;

but he deserves to be gratefully remembered for his *Traité du Calcul Différentiel et Intégral* (Paris, 1797), a work on which he spent immense labour, in order to make it a complete and harmonious compilation of the results of all previous research. The value of such a work may be estimated by Laplace's statement, that it cost him ten years' labour to supply for himself the want of such a work. L.'s other writings are treatises on Arithmetic, Algebra, Geometry, Trigonometry, Probabilities, Land-surveying; Geography, Mathematical and Physical, &c.

LA CROSSE is the name of a field game played with a ball. The Iroquois Indians have been long accustomed to play it in Canada; and some of them exhibited their skill in the game in presence of the Prince of Wales, when he was in that colony in 1860. Eighteen of those Indians, Anglicised in many of their habits and customs, came to England in July 1867, to play the game in a country where it was not before known.

In what way La Crosse differs from golf, hockey, foot-ball, and other games, may be briefly explained. Every player is provided with a kind of large battledore. This consists of a long stick of light hickory, bent at the top like a bishop's crozier; strings of deer-skin are stretched diagonally across the hooked portion in different directions, forming a network—not so tightly as in a regular battledore or racquet-bat, nor so loosely as to form a bag. As the battledore, called the *crosse*, is five or

obtain a mastery over the ball, and convey it to the opponents' goal. When scooped up from the ground, it is carried horizontally on the *crosse*, the player running one of the goals, trying to elude the vigilance of his antagonists. If it seems prudent, he pitches the ball off his *crosse* towards a colleague, who may be in a better position to convey it towards the goal. The ball is not touched by the hand, except under special and clearly-defined circumstances. If the ball be accidentally driven through the red goal by one of the reds, the blues win the game; and *vice versa*. The players must not strike, trip up, or grasp one another; nor must any one lay hold of the *crosse* of another. One player strikes the ball off an opponent's *crosse* with his own *crosse*, and not by any other means. Two players on the same side may fling or carry the ball consecutively.

It will thus be seen that there is a little of cricket, of football, of hockey, and of racquet in La Crosse. The goals present some analogy to wickets in cricket; the occasional struggle for the ball is like the 'scrimmage' of football, though not so rough and dangerous; the general mode of play may be compared to hockey; while the battledore claims some resemblance to the racquet-bat. There is nevertheless sufficient originality in the game to render it wholly a distinct one. La Crosse Clubs have already been established at Blackheath and Richmond.

LADY FERN (*Athyrium filix femina*, or *Asplenium filix femina*), a beautiful fern, common in moist woods in Britain, with bipinnate fronds sometimes two feet long. The whole plant has an extremely graceful appearance. It is said to possess the same anthelmintic properties as the male fern.

LA'GOS, a town of Africa, on the coast of Upper Guinea, 150 miles west of Benin, at the west end of a long low island, which lies at the entrance to a lagoon of the Bight of Benin, near the mouth of the river Ogun. A number of English and other traders reside here, and the town contains many good houses built in the English style. L. was formerly a notorious seat of the slave-traffic. It was captured and destroyed by the British in December 1851, and a treaty was concluded by which the ruler guaranteed freedom of commerce, the protection of Christianity, and the abolition of the slave-trade and of human sacrifices. Pop. 6000. L. since 1861 has been a British possession. Value of imports (1862), £77,933; exports, £61,932.

LALITA-PATA'N, or PATAN, a town of Nepal, four miles south from Khatmandu, from which it is separated by the Bognutty. L. was formerly the capital of a small independent state. It is a neat town, and has some good public buildings. It has manufactures of cotton, copper, and brass. Pop. supposed about 24,000.

LALLY-TOLENDAL, THOMAS ARTHUR, COUNT DE, a French general, of historic note as the victim

The Crosse and Ball.

six feet long, there is great leverage power in handling it. Only one ball is employed, made of india-rubber, and eight or nine inches in circumference. Posts or poles about six feet high, with a small flag at the top of each, complete the equipment. The players divide themselves into two parties, the reds and the blues; their number, as well as the size of the play-field, are nearly optional, more players being needed as the area is larger. Red predominates in the dress of one party, and blue in that of the other, for facility in distinguishing colleagues from opponents. To prepare for the game, a red goal is set up at one end of the field, consisting of two small red flags on posts, about six feet high and six feet apart; a similar goal, but blue in colour, is set up at the opposite end of the field. Now, the object of the game is, for the blues to drive the ball through the red goal, and the reds to drive it through the blue goal; and each party, of course, strives to frustrate the plan of the other. The ball is not thrown by the hand, but is hooked up from the grass by the bent end of the *crosse* or battledore; it is borne on the netting horizontally, while the player runs, and is dexterously thrown off the *crosse* when the exigencies of the game require such a manoeuvre. No player is allowed to wear spiked shoes; but a good hold of the ground is obtained by wearing moccasins, which the Indians prefer, for the purpose, to regular shoes.

In the arrangement of the men on each side, the *goal-keeper* defends the goal; *point* is the first man out from the goal; *cover-point* is a little in advance of point; *centre* is in the centre of the field; *home* is the player nearest to the opponents' goal; while the *fielders* comprise the rest of the players. Beginning near the centre of the field, the players struggle to

Frond of the Lady Fern (*Athyrium filix femina*).

LAMBAYEQUE—LAPÉROUSE

of a judicial murder, was born in Dauphiné in 1698. His father, Sir Gerard Lally, was an Irish Jacobite refugee, and commander of an Irish regiment. L. distinguished himself much as a soldier in Flanders; accompanied Prince Charles Edward to Scotland in 1745; and in 1756, was made a lieutenant-general and appointed commander-in-chief in the French East Indian settlements. He commenced hostilities against the British in India, took many places, and besieged Madras itself; but sustained a severe defeat under the walls of Vindarachi, and was compelled to retreat to Pondicherry, which was attacked in March 1760 by land and sea by a greatly superior British force. Lally, however, held out for ten months; and before Pondicherry fell, on 16th January 1761, the sufferings of its defenders were terrible. L. was conveyed as a prisoner of war to England; but hearing that he had been accused in France of betraying his trust in India, he obtained leave to proceed to France for the vindication of his character. An investigation was promised, but no step was taken for a year, and then Lally was only thrown into the Bastille, where he remained 19 months before his trial took place. The parliament of Paris at last, on 6th May 1766, condemned him to death for betraying the interests of the king and the Indian Company, and the sentence was executed three days after. But his son, supported by the powerful assistance of Voltaire, procured a royal decree on 21st May 1778, declaring the condemnation unjust, and restoring all the forfeited honours.—The son, TROPHIMUS GERARD, MARQUIS DE LALLY-TOLENDAL, was born in Paris, 5th March 1751. He was one of those nobles who, in the States General, in 1789, united with the Third Estate; but alarmed at the democratic tendencies of the National Assembly, he afterwards allied himself more with the court. He laboured to procure for France a constitution with two chambers and a privileged aristocracy. He earnestly sought to protect the king, but was himself obliged to flee to England. After the Revolution of 18th Brumaire, he returned to France and lived at Bordeaux. Louis XVIII. made him a peer; but he remained true to his political principles, and defended constitutional liberty. He died on 11th March 1830. He was the author of a Defence of the French Emigrants, which made a great sensation in France at the time of its appearance, and of many other pamphlets.

LAMBAYE'QUE, a town of Peru, in the dep. of Libertad, near the mouth of the river Lambayeque, 425 miles north-west from Lima. It is about five miles from the sea; but has some trade, although its roadstead is very bad, and fully a mile from the shore. L. has a church and several chapels. It has manufactures of cotton fabrics. Pop. 8000.

LAMO'V, or **LOMOV**, the name of two towns of European Russia, in the government of Penza, and on the river Lamov, a branch of the Mokscha, which itself is, through the Oka, a feeder of the Volga. Verknii L. (Old, or Upper L.) is about 64 miles west-north-west from Penza. It has seven churches. Pop. (1863) 7944.—Nijni L. (New, or Lower L.) is nine miles south-west from Verknii L., further down the river. It has three churches, and an annual fair, which attracts traders from all parts of Russia. Pop. (1863) 9630.

LAMPEDU'SA (anc. *Pelagia*), a small uninhabited island in the Mediterranean Sea, about midway between Malta and the coast of Tunis. It belongs to the kingdom of Italy, having been formerly a dependency of Sicily. It is about seven miles in length, and in most places not quite one mile in breadth, its circuit being about 13 miles. The western part of the island is covered

with dwarf olives; and these and other shrubs supply great quantities of firewood, both to Tripoli and Malta. Great numbers of wild goats inhabit the island. L. was at one time inhabited. Near it are the two ialets of Limpione and Linoea.

LANDED ESTATES' COURT. See **INCUMBERED ESTATES' COURT.**

LANDERNEAU, a small seaport town of the dep. of Finistère, France, 13 miles north-east from Brest. Only a few small vessels belong to the town, although about 700 enter and clear the port annually. The harbour admits vessels of 400 tons. Pop. (1866) 6396.

LA'NSKRONA, a fortified seaport town of Sweden, on a tongue of land which projects into the Sound, 18 miles north-north-east from Copenhagen. The harbour is very good. Ship-building is carried on. Corn, fish, tar, pitch, timber, and alum are the principal exports. Pop. (1864) 6598.

LANGENBECK, BERNHARD VON, Professor of Surgery in the University of Berlin, director of the Royal Clinical Hospital, and general staff physician of the army, is nephew of the famous surgeon, Max Langenbeck, in Göttingen. Having been appointed (1847) successor to the great operator, Dieffenbach, in Berlin, he was not long in acquiring an equally high celebrity, especially through his great skill and success in the operation for harelip, as well as in the replacement of noses, eyelids, and lips. He likewise earned a great reputation through his execution of the operation of Resection (q. v.), in which the diseased or injured part only of a bone is removed, instead of the whole limb perhaps being amputated. During the late wars in Germany, a great field opened itself for this kind of operation, and hundreds of the wounded who came under the knife of L. have to thank him for the preservation of their limbs. On account of his eminent services, he was ennobled, and received the highest medical rank in the Prussian army.

L. is a man of prepossessing appearance; and instead of that bluff harshness which, whether natural or assumed, has characterised so many great surgeons, he is eminently tender and sympathetic with his patients. As a teacher, he is highly successful; and the Clinical Hospital in Berlin, under his personal direction, is the resort of patients from all countries of the world.

LA'NGNAU, a town of the canton of Bern, Switzerland, 15 miles east from Bern, in the Emmenthal. It is situated on the Ilfis, a branch of the Emmen. Weaving is carried on to some extent, and L. is the principal mart for the cheese and linen thread of the Emmenthal. Pop. (1860) 5860.

LAP-DOG, a name common to all those diminutive varieties of dog which are kept as drawing-room pets, and which ladies take with them in their carriages. Most of them are Spaniels (q. v.), as the King Charles's Spaniel, the Maltese Dog, &c. Gentleness of disposition, large ears, and long hair, are among the approved characteristics of lap-dogs. The very smallest of the race is the MEXICAN LAP-DOG.

LAPÉROUSE, JEAN FRANÇOIS DE GALAUF, COUNT DE, a famous French voyager, born near Albi, in Languedoc, now in the dep. of Tarn, in 1741; attained the rank of captain in the French navy; and was sent, in 1782, to destroy the British forts or settlements in Hudson's Bay. In this expedition he showed a remarkable power of contending with difficulties, and accomplished his object notwithstanding the storminess of the sea and the ice in which it abounded. He signalised himself also by his humanity towards the occupants

of the forts which he destroyed. He was now chosen to command an expedition of discovery sent out by the French government. He sailed, in August 1785, with two ships, visited the north-west coast of America, explored the north-eastern coasts of Asia, and made important discoveries in that region, although he failed to discover that object of so many expeditions, the North-west Passage. In February 1788, he anchored in Botany Bay, after which no trace of him was obtained, although the French government offered a reward of 10,000 francs for information, and sent out an expedition under D'Entrecasteaux, in 1791, to search for him, until, in 1826, the captain of an English vessel, Captain Dillon, found on the island of Tucopia—a very small island to the north of the New Hebrides—a number of things which had belonged to L.'s ships, and which had been obtained from the inhabitants of the island of Mallicollo, one of the New Hebrides. Investigation being made by the East India Company, which sent Captain Dillon for this purpose, and, subsequently, by the French government, which sent out an expedition commanded by Dumont d'Urville, eye-witnesses were found of the destruction of two French ships on the coast of Mallicollo, and five French cannons and other remains of the expedition were found there. It was fully ascertained that both of L.'s ships had been wrecked in a storm on a coral reef, and that all on board had perished. Dumont d'Urville erected a simple monument with a brief inscription in memory of his ill-fated countrymen. The account of L.'s voyage, published under the title of *Voyage autour du Monde* (4 vols. Par. 1797, with atlas), was prepared by order of the French government, from the journals which were sent home by him from Kamtschatka. But the collections and note-books of the naturalists who accompanied the expedition, perished along with themselves.

LA'RNICA (anc. *Cithium*), a town of the island of Cyprus, in N. lat. 34° 55' and E. long. 33° 37', situated in a marshy plain, about a mile from a bay on the south coast of the island. Owing to its filthy condition and the neighbouring marshes, L. is a very unhealthy town. Water is very scarce, and is supplied by an aqueduct. L. is, however, a place of considerable trade, the chief seat of the commerce of the island, and the residence of European merchants and consuls. There is regular steam-boat communication with Constantinople, Smyrna, Alexandria, and Marseille, and occasionally with Liverpool. There is no proper harbour; but the bay affords good anchorage. The principal exports are wheat, cotton, silk, wine, and drugs. There are many remains of antiquity in and around the town. Pop. 10,000.

LATREILLE, PIERRE-ANDRÉ, an eminent naturalist, particularly distinguished as an entomologist, born 29th November 1762, at Brive, in the province of Limousin, now in the dep. of Corrèze, France. He was descended of a noble family, but was left an orphan at an early age, and with very slender means of subsistence. In 1778, he was placed in the college of Cardinal Lemoine, at Paris, to be educated for the church. Whilst here, he acquired the friendship of Haüy (q. v.). He now began to devote himself almost exclusively to the study of insects. He completed his education for the church, and received ordination—a circumstance which afterwards, in the days of the Revolution, exposed him to much hardship and danger. He gave himself, however, chiefly to entomological studies. His first publication was on the *Mutillas* of France, insects of the order *Hymenoptera* (1792); which was followed by very

many other works of the same kind, articles in encyclopædias, magazines, &c. In 1796, he published, at Brive, his first great work, *Précis des Caractères Génériques des Insectes, disposés dans un Ordre Naturel*. It was an important step towards a truly natural system of entomology, although really a mere sketch of a system. An interesting incident falls here to be mentioned. During the fury of the French Revolution, L. was condemned to *déportation*, and sent to prison at Bordeaux, awaiting the execution of his sentence. The surgeon who visited the prison observing the prisoner attentively looking at a small insect (*Necrobia ruficollis*), was informed by him that it was very rare, and that he wished to transmit it to two young naturalists in Bordeaux. His wish was gratified, and the young naturalists—MM. Dargelas and Bory de Saint-Vincent—exerted themselves to obtain his release, in which they ultimately succeeded. L. always remembered this with great gratitude, and has commemorated the incident in some of his works. A figure of the insect is engraved on his tomb. L. was again in danger in 1797, when he was proscribed as an *émigré*; but again he escaped through the influence of friends. Having, after the Revolution, relinquished all thoughts of the church, he entirely devoted himself to natural history; was received as a corresponding member of the Institute; and was employed in the arranging of insects in the Museum of Natural History. He died at Paris, 6th February 1833, at the age of 70. His works on natural history are very numerous. The most important, besides those already noticed, are: *Histoire des Salamandres* (Par. 1800); *Histoire Naturelle des Singes* (2 tom., Par. 1801); *Essais sur l'Histoire des Fourmis* (Par. 1802); *Histoire Naturelle des Reptiles* (4 tom., Par. 1802); *Genera Crustaceorum et Insectorum* (4 tom., Par. 1806—1809); *Considérations sur l'Ordre Naturel des Animaux*, &c. (Par. 1810); *Familles Naturelles du Règne Animal* (Par. 1825); *Cours d'Entomologie* (2 tom., Par. 1831—1833). L. contributed greatly to the present natural system of entomology; and his labours in other departments of natural history were not inconsiderable.

LAUENBURG, a town of Prussia, in the province of Pomerania, 38 miles west-north-west from Danzig. Manufactures of woollen and linen cloth, and of white and common leather, are carried on. Pop. (1864) 5797.

LAU'RIA, a town of Italy, in the province of Potenza (formerly Basilicata), 98 miles south-east-by-east from Naples, and about five miles from the shore of the Gulf of Policastro. Opposite to it is the imposing mass of Monte Sirino. L. is an ancient town, but still of considerable prosperity. Woollen manufactures are carried on. Pop. (1861) of L. Superiore, 4791, and of L. Inferiore, 4258; total, 9049.

LAURVIG, a seaport town of Norway, situated at the head of a small fiord, which branches off from Christiania Fiord. The town of L. has of late rapidly increased in population and prosperity. It carries on a considerable trade with foreign countries, and particularly with Britain. Very extensive iron-works—the Fritzo iron-works—are situated near the town. A cannon-foundry gives employment to many operatives. There are also snuff-manufactories and distilleries. The harbour is excellent, and suitable for the largest vessels. Pop. 4944.

LA VILLEMARQUÉ, THÉODORE-CLAUDE-HENRI HERSART, VICOMTE DE, a Breton antiquary and Celtic scholar, was born at Quimperlé, in Bretagne, on the 6th July 1815. Representing an old

family of his native province, his attention was early turned to its antiquities and its peculiar language and literature. His first important work was a collection of popular Breton songs and melodies, published in 1839, with a French translation and notes, under the title of *Barzaz-Breiz*. Three years afterwards appeared his *Popular Tales of Bretagne*, to which was prefixed a dissertation on the story of the Round Table. His next work was a collection of the poems of the Celtic bards of the 6th c., with a French translation, and explanatory and critical notes (1850). This publication made the labours of La V. widely known. He was appointed a correspondent of the Academy of Berlin, and a member of the French Institute (Academy of Inscriptions and Belles-Lettres). La V. has since published a work entitled the Celtic Legends (*La Légende Celtique*) of Ireland, Cambria, and Bretagne, which contain such of the original texts—Irish, Welsh, or Breton—as are rare or unpublished. La V. is the author or editor of several other works connected with the Celtic literature and languages, among which are a *Breton Grammar*, a *Breton and French Dictionary*, *Bretagne Ancient and Modern*, and *The Great Mystery of Jesus*, with a dissertation on the dramatic literature of the Celts. In all these works, La V. gives evidence of laborious and painstaking scholarship. At times, he does betray an enthusiasm which seems exaggerated; but this will be readily pardoned in a local antiquary and successful pioneer in a new field of research. Some of his works have been translated into English by T. Taylor.

LAWRENCE, SIR WILLIAM, a distinguished surgeon, was born at Cirencester, in Gloucestershire, in July 1783. He received a classical education at a school in his native county; and, in 1790, went to London, where he became an inmate in the house of Mr Abernethy, to whom he was apprenticed. Abernethy was so impressed with the zeal and capacity of his pupil, that in the third year of his apprenticeship he appointed him demonstrator in anatomy to the hospital (St Bartholomew's)—a situation which he held with great credit for twelve years. In 1805, he received his diploma from the Royal College of Surgeons; in 1813, he was appointed surgeon to St Bartholomew's; and became full surgeon in 1824. In 1813, he was elected a Fellow of the Royal Society; and, within the two following years, filled the posts successively of surgeon to the Eye Infirmary in Moorfields, and surgeon to the Royal Hospitals of Bride-well and Bethlehem. In 1815, he became one of the professors of anatomy to the Royal College of Surgeons, where he delivered lectures for four years. In 1828—1829, he succeeded his teacher, Mr Abernethy, as lecturer on surgery to St Bartholomew's. From this period, L. took an active share in the great questions of reform, which divided the medical world as much as the political, and played the part alternately of an advocate and an opponent of innovation. He made many enemies, among whom came to be numbered his old master, Abernethy, whom he offended by his advocacy of philosophical materialism. Nevertheless, he continued to enhance his reputation as a surgeon and his position as a practitioner, and contributed many valuable works to the literature of his profession. He succeeded Sir Benjamin Brodie as serjeant-surgeon to the Queen, on which occasion he received his baronetcy. He was one of the best, as he was also one of the last representatives of that great school of surgeons, of which Cline, Abernethy, Brodie, Astley Cooper, Ker, and Liston were the leaders. He died of paralysis, at the age of 83, in Whitehall on the 5th July 1867. His writings, which

are very numerous, are chiefly the following: *A Description of the Arteries of the Human Body, reduced into the form of Tables*, translated from the Latin of Adolphus Murray, Professor of Anatomy at Upsal; *The Treatment of Hernia*; *An Introduction to Comparative Anatomy and Physiology, being the Introductory Lecture delivered at the Royal College of Surgeons in 1819*; *A Treatise on the Venereal Diseases of the Eye*; and *A Treatise on the Diseases of the Eye*, in general, &c. Of these works, the most important for his reputation and for the profession are those on the venereal diseases of the eye, and on hernia.

LAYAMON, also LAWEMAN, author of the *Brut*, a metrical chronicle of Britain from the arrival of the fabulous Brutus to the death of King Cadwallader, 689 A.D., was, he himself tells us, a priest at Ernely, on the Severn, in Worcestershire, and appears to have flourished about the beginning of the 13th century. Nothing more is known concerning him. The value of the *Brut* is not so much literary as linguistic. It has no high pretensions to originality, being confessedly a compilation from Bede, St Augustine (of England), St Alban, and more particularly Wace, the Anglo-Norman poet, of whose *Brut d'Angleterre* it is in fact mainly an amplified translation. But Wace's performance is itself only a translation, with additions, from Geoffrey of Monmouth's Latin *Historia Brittonum*; and that again at least declares itself to be in turn a translation from a Welsh or Breton original (see GEOFFREY OF MONMOUTH). It will thus be seen that L.'s work is only a third reproduction of a Celtic story; but in justice to the author, it must be stated that his version is more poetical and dramatic than those of his predecessors. The great value of the poem, however, is, as we have said, linguistic rather than literary. It shows us the Anglo-Saxon changing or changed into Early English, and a study of its peculiarities of grammar and phraseology enables us to trace the process by which the Saxon of Alfred and the Chronicle became transformed into the English of Chaucer and Wicliffe. One curious and important fact is determined by it—viz., that 200 years after the Norman Conquest, the use of words of French origin—so marked a feature of Chaucer's diction—had scarcely begun. In the 32,250 lines which the poem contains, there are not more than 50 such words. The versification is very arbitrary, exhibiting sometimes the alliteration of Anglo-Saxon, and sometimes the rhyme of French poetry. The work was edited (with a literal translation, notes, and a grammatical glossary) for the Society of Antiquaries of London by Sir Fred. Madden (Lond. 3 vols. 1847).

LEAPING-FISH (*Salarias tridactylus*), a curious little fish of the Blenny family, abounding on the coast of Ceylon, and remarkable for leaving the water to visit every place washed by the surf. By the aid of the pectoral and ventral fins, and the gill-covers, it moves across the damp sand, ascends the roots of mangroves, and runs up wet rocks in quest of flies. 'These little creatures are so nimble,' says Sir J. E. Tennent, 'that it is almost impossible to lay hold of them, as they scramble to the edge, and plunge into the sea on the slightest attempt to molest them.' They are three or four inches long, and of a dark brown colour.

LEATHER-CLOTH is one among many names given to manufactured fabrics intended to possess most of the good qualities of leather, without being so costly. As far back as 1849, a material under this name was invented in America; and many specimens of it were placed in the Great Exhibition of 1851. In 1855, a factory for making it was

established at West Ham, in Essex, and the operations are still conducted there on a scale equal to the production of 10,000 or 20,000 square yards per day. Linseed oil is heated in large coppers to a certain high temperature, then removed to cool; then mixed with other ingredients, two of which are turpentine and lampblack. This composition is used as a kind of varnish to be applied to the surface of unbleached cotton. The cotton, woven to various widths and lengths, is calendered to make it smooth, and then passed over a roller; the composition is applied to it, and a peculiar kind of knife scrapes the layer to an equable thickness and a smooth surface. After being dried in a heated oven, the cloth is passed between rollers covered with pumice-dust, to rub the composition smooth. These processes are repeated four or five times. The cloth is next painted three or four times with a kind of enamel paint. Some kinds are grained like morocco leather, by being passed between rollers peculiarly grooved on the surface; others receive a pattern in relief by passing between embossing rollers; while the specimens intended for furniture-hangings and table-covers are printed in gold and colours. The uses of this leather-cloth are numerous. The United States army, in 1862, had capes, leggings, and knapsacks made of it.

The leather-cloth made on Seager's patent is in fact leather, not cloth. It consists of leather parings and shavings, reduced to a pulpy mass, and moulded to any useful or ornamental forms, such as machinery-bands, buckets, architectural ornaments, picture-frames, &c. It may be made either hard or pliant, according to the mode or degree of pulping. Messrs Spill's *vegetable leather* is made chiefly of caoutchouc and naphtha; the smell of the latter is removed by chemical treatment; and the sheets made are thickened to any degree by successive backings of canvas. The material is tough, resists damp, and takes a polish, and is available for bookbinding, library table covers, carriage aprons, soldiers' belts, harness, and other purposes. Szerelmy's leather-cloth is, like some other kinds, an application of oily pigments to cloth; according to the nature of the textile used as a backing (cotton, linen, woollen, silk, or alpaca), and to the mode of applying the surface composition, the material becomes an imitation of morocco, of calfskin, of enamel leather, or of waterproof cloth. Le Jeune's *leather substitute* consists of a cement or mastic of caoutchouc or of gutta percha on cloth, felt, or leather, pressed by rollers, and then pressed upon a layer of leather. By a peculiar splitting machine, a thin sheet is produced with an extremely thin layer of leather upon it. Another cloth is then cemented to the remaining leather, followed by another splitting; and so on till the leather is exhausted. The cloth enables the leather to be split thinner than would be otherwise practicable. The resulting substance, therefore, is really leather on one side, and may be dyed and embossed in various ways; the intervening caoutchouc or gutta percha renders it waterproof. Beard and Downing's *Artificial Leather* consists of an open linen fabric, upon which a fleece of cotton or wool fibres is cemented by a composition of oil and resin, pressed down by rollers; two or more successive layers of fleece and cement thicken the substance. Ground leather is sometimes mixed with the fleece, and the surface will receive any of the usual oil colours.

These various substances, it will be seen, are intended in most cases as substitutes for leather, but in others as a kind of floor-cloth. There are certain points of difference between all of them and Linoleum (q. v. in SUPPLEMENT).

LEBRIJA (anc. *Nebriasa-Veneria*), a town of Spain, in the province of Seville, 34 miles south by west from Seville, on an affluent of the Guadalquivir, and on the railway between Seville and Cadiz. It is pleasantly situated on a slight eminence, which overlooks a plain liable to be overflowed by the Guadalquivir and its branches. A large church, originally a mosque, exhibits a strange combination of the Arabic, Roman, and Gothic styles. L. is famous for its oil. There are manufactures of woollen cloth, hempen fabrics, glass, pottery, bricks, tiles, and soap. Pop. 7741.

LECTIONARY (Lat. *Lectionarium*), one of the service-books of the medieval church, so called because it contained the lessons (*lectiones*) of the church-service. Of these there are two which deserve special notice. The first is the so-called 'Roman Lectionary,' which contained the epistles and gospels of the Roman missal, and sometimes all the lessons of all the various services in use in the Roman Church, in which case it was named the *Plenarium*. The most ancient form of the Roman Lectionary was called 'Comes' or 'Liber Comitit.' Its compilation was attributed to St Jerome, and it appears certain that it belongs in substance, although not in form or in details, to that age. The collection was revised and remodelled in the 8th century. The second of the ancient lectionaries is that known as the Gallican Lectionary, which was published by Mabillon from a MS. of the monastery of Luxeuil, and which is believed to represent the rite of the ancient Gallican Church, chiefly because one of the few saints' offices which it contains is that of the peculiarly French saint, Geneviève. It is interesting as shewing that the Gallican liturgy had three lessons, and not two, as in the Roman missal. Unfortunately, Mabillon's MS. of this highly interesting relic of ancient Gaulish Christianity is imperfect, and no other has since been discovered.

LEER, a town of Prussia, Hanover, in East Friesland, 32 miles west-north-west from Oldenburg, on the right bank of the Leda, near its junction with the Ems. There are manufactures of linen, hosiery, &c.; breweries and distilleries; and ship-building yards. A railway, opened in 1856, runs northwards to Emden, and southwards to Papenburg, Osnabrück, and Münster. Pop. (1864) 8825.

LENGA'GO, a fortified town of Northern Italy, in the province of Verona, on the left bank of the Adige, 22 miles south-south-east from Verona. It has manufactures of hats and leather, and a considerable trade in wheat and rice. The cultivation of rice is extensively prosecuted in the neighbourhood, and tends to increase its natural unhealthiness. The country is swampy, and intermittent fevers prevail. Pop. 10,318.

LEIPA, or LEIPPA, a town of Bohemia, 42 miles north-north-east from Prague, situated not far from the right bank of the Polzen, a branch of the Elbe. L. has an Augustine monastery. It is a place of considerable industrial activity, having manufactures of woollens, cotton, glass, and earthenware. Pop. 8442.

LEITMERITZ, or LITOMIERCZICZE, an old walled town of Bohemia, on the right bank of the Elbe, 34 miles north-north-west from Prague. The situation of the town is beautiful, on the slope of a hill which rises from the river. One of the churches has a tower shaped like a cup, a curious memorial of the fierce religious contests which raged in Bohemia in the 15th c., and in which the question of the use of the cup by the laity in the sacrament of the Lord's Supper had so great prominence. Much of the Bohemian glass is polished in L., and

it has an active trade in corn, wine, fruit, and fish. Straw hats and chicory are also among its articles of produce. It is celebrated for a kind of apple called the *Borsdorf*, which is sent in large quantities both to Berlin and St Petersburg. Pop. 7488.

LEITOMISCHL, or LEUTOMISCHEL, a town of Bohemia, 84 miles east-south-east from Prague. It stands on the left bank of the Laucha, an affluent of the Elbe. A castle, erected in the 16th c., is esteemed one of the finest buildings of its kind in Bohemia. L. has manufactures of linen, and an active trade in corn, fish, and wine. Pop. 7037.

LE'NNEP, a town of Rhenish Prussia, 22 miles east-south-east from Düsseldorf, in a beautiful valley, on the Lennep, an affluent of the Rhine. It is a principal seat of the woollen manufacture, and the cotton manufacture is also carried on. Pop. (1864) 7253.

LENS (anc. *Elena* or *Lenense*), a town of France, in the dep. of Pas-de-Calais, on the Souchez, a feeder of the Scheldt, 17 miles south-south-west from Lille. It is a place of great antiquity, and was once strongly fortified. It is famous for the great victory gained by the Prince of Condé over the Germans and Spaniards, under its walls, in 1648. In the neighbourhood of L. are coal-mines, lime-works, and brick-works. Pop. (1866) 5738.

LEPTISMA, a genus of wingless insects, of the order *Thysanura*. The best known species is *L. saccharina*, sometimes called the *Sugar Louse*, because it is often found about old sugar barrels. It is said to have been introduced into Britain from America. All the species of L. and of the family *Lepismida* inhabit moist places, and feed on decaying vegetable substances. They have a flattened, spindle-shaped body, terminating in three long bristles. They run swiftly. They are mostly covered with silvery scales, which are much used as test objects for the microscope.

LEROARA DE' FREDDI, a town of Sicily, in the province of Palermo, 30 miles south-south-west from Palermo, in an inland mountainous district. Most of the inhabitants are employed in the sulphur mines of the vicinity; and the road to Palermo is much occupied by carts carrying sulphur for exportation. Pop. (1861) 9007.

LESSON (Lat. *lectio*, Fr. *leçon*, a reading, called by the Greeks *anagnosma*), in Liturgical Literature, means a portion of the church service appointed to be read, chiefly with a view to instruction and exhortation, not couched in the form of a prayer, nor, even when found in the mass or the communion service, directly bearing upon the consecration of the Eucharistic elements. The lessons of the Eucharistic service in the Roman Catholic Church are always taken from the books of the Old or New Testament (including the Apocrypha); but in some of the other services of the Roman, Greek, and Oriental churches, portions of the writings of the Fathers, lives of saints, and occasionally short narratives from church history, are employed. The very earliest notices which we have of the liturgical services of the first Christians, allude to the usage of reading portions of sacred Scripture publicly in the church. The practice existed among the Jews in their synagogues (Luke iv. 16), and St Paul frequently alludes to its use also in Christian assemblies, in his epistles to the infant churches of Colosse, Laodicea, and Thessalonica. It is even more circumstantially referred to by Tertullian (*Apolog.* c. 39; and again, *Prescript.* c. 36), and by Justin the Martyr in his *Apology* (1 *Apol.* n. 67). Our information regarding the liturgy of this early period is too

scanty to enable us to say what order was followed, and what principles were adopted in selecting the portions of Scripture for these solemn readings; but from the Fathers of the 4th and later centuries, it is plain that the selection was in some degree regulated by the seasons; and, at all events, that it was not left to the determination of each individual minister or even church. It would seem that in general the extracts were so disposed as to present the several books of Scripture in succession; but at particular times, portions were chosen which seemed appropriate to these times. Thus, the lessons at and after Easter were the Gospel narratives of the Resurrection; between Easter and Pentecost, the Acts of the Apostles; in Lent, they were taken from Genesis and the other books of the Pentateuch; in Passion-tide, from the Book of Job. In the modern Greek Church, so strictly is this order observed, that the Sundays of certain periods are known by the names of the Evangelists read at that time—as the first, second, or third 'Matthew-Sunday,' 'Mark-Sunday,' &c. In the Roman missal, the distribution of the Gospel lessons is regulated more by the subjects than by the authors; and in addition to the distribution according to time, there is another which is regulated by the nature of the festivals, or the special characteristics of the saints to whose offices they are appropriated. The time and the origin of this distribution are uncertain; but it is commonly ascribed, at least in part, to St Jerome, and distinct traces of it are found in several writers of the 5th and following centuries.

In the service-books of the Roman Catholic Church, the lessons of the missal are always from Holy Scripture; and they are, unless in a few exceptional cases, two in number, the first called (as being ordinarily taken from one of the Epistles of St Paul, or the canonical epistles) the 'Epistle;' the other, the 'Gospel.' A second Gospel is commonly read, which is taken from the 1st chapter of St John. The Epistle is taken either from the canonical epistles of the New Testament, or, less frequently, from one of the books of the Old Testament, including the Apocrypha (generally from Wisdom, Ecclesiastes, Ecclesiasticus, or Proverbs), but occasionally from the books of the Pentateuch and other historical books. On a few exceptional occasions, chiefly in Advent and Lent, or at the Quarter Tenses (as the Ember-days are named in the language of the Roman Church calendar), more than one Epistle occurs. The distinction of the 'Epistle Lesson' and the 'Gospel Lesson' is at least as ancient as the time of St Augustine (see Aug. Serm. 176). In the solemn or high mass, each of these lessons is chanted or recited by a separate minister—the Epistle by the sub-deacon, the Gospel by the deacon; the former being chanted at the right side, the latter at the left side of the altar. In the low mass, both are read by the priest; but the same difference of position in reciting them is observed by the single priest. Anciently, one or both were chanted from an elevated platform or pulpit called *ambo*, and in Gothic churches, from a gallery attached to the rood-screen. The recitation from the *ambo* is retained in the Ambrosian rite as still practised in the Milan Cathedral. In the several Eastern rites, the lessons are more numerous than those corresponding to the Roman Epistle, being chosen from the Old Testament, from the Acts of the Apostles, from St Paul's Epistles, and from the Catholic epistles. The Gospel-lessons are, of course, taken from the several Evangelists. In the Greek Church, the former is read by the *anagnostes* or *lector*; the latter by the deacon. In the other Eastern churches, both are read by the deacon, with the exception of the Syrian Church, in which the

Gospel is read, not by the deacon, but by the priest.

The 'lessons' of the Roman breviary are more varied. They occur only in matins, with the exception of a 'short lesson' which is found in Prime and also in Compline. The lessons of matins are sometimes three, sometimes nine in number, according as the matins consist of one or of three 'nocturns.' See BREVINARY. When there are three nocturns, the lessons of the first are commonly from the Holy Scriptures, the books of which are so distributed throughout the seasons, that portions of every book shall be read during the year. The lessons of the second nocturn consist either of a narrative of the life of a saint, or of the circumstances of a festival, or of a sermon or other discourse from a holy Father; and those of the third are generally from a homily of one of the Fathers upon the Gospel appropriate to the festival. The 'short lessons' of Prime and Compline consist of sentences from Holy Scripture.

In the public and solemn offices, the lessons are chanted, the tones being reputed of ancient origin; and the chanting of the Gospel especially being accompanied with special marks of reverence for the word of God, as the incensation of the book of the Gospel, signing it with the sign of the cross, and the bearing of lights during the singing—a practice which was already ancient as early as the days of St Jerome's controversy with Vigilantius. When the pope officiates solemnly, the Epistle and Gospel are chanted in Greek as well as in Latin, in order to denote the union of both the rites in one Catholic Church; and at the coronation of at least one of the popes (Alexander V.), the Gospel was sung in Latin, Greek, and Hebrew.

In the Church of England the term is used only of the portions of Scripture appointed to be read at morning and evening prayer, and at the service for the burial of the dead. The enlargement of this part of the service formed a great feature of the Reformed liturgy, and was a return to the more ancient use, entire chapters being substituted for short selected passages. Four lessons are appointed for every day, two at morning and two at evening prayer. The first lesson, at each service, is taken from the Old Testament—which is read through, in course, once a year (the order of the books being only departed from in the reservation of Isaiah for the season of Advent)—and from certain books of the Apocrypha, viz., Tobit, Judith, Wisdom, Ecclesiasticus, Baruch, and the histories of Susanna and of Bel and the Dragon, which are read for the reasons quoted from St Jerome, in the Sixth Article of Religion, viz., 'for example of life and instruction of manners,' but not 'to establish any doctrine.' The second lessons are from the New Testament, which is read through three times in the year—that in the morning from the Gospels and Acts of the Apostles, that in the evening from the Epistles. 'Proper,' i. e., special first lessons, are appointed for all Sundays and holidays; those for Sundays were fixed at the restoration of the Reformed liturgy under Elizabeth, and consist of chapters selected from the various books, so arranged as to follow the seasons of the Church—a. g., those during Advent are taken from Isaiah, those from Septagesima to Easter from Genesis and Exodus, so that the account of the institution of the Passover, and the going out from Egypt, falls on Easter Day. The general purpose of the Sunday proper lessons, seems to be that of representing the divine dealings with the Church of the Old Testament. The first lessons, on the minor holy-days, are taken, in course, from the didactic books of the Old Testament and Apocrypha. Except on the chief festivals, there are no proper second lessons, the New Testament

being ordinarily read through, in course, on Sundays and week-days, so causing the fixed first lesson to combine with the varying second lesson, in a manner which sometimes throws much light on both. Parts of Leviticus and Joshua, and the two books of Chronicles, are omitted; and the Apocalypse is resorted to, only to supply the second lessons for the feast of St John the Evangelist, and at evening service on All Saints' Day. The lessons for each service are ascertained by reference to a calendar, prefixed to the Book of Common Prayer—the proper lessons, which always supersede the others, being given in separate tables. When a lesson is directed to be read to any verse, it is always *exclusive* of that verse. The lessons are allowed to be read by persons not in holy orders, but are directed to be so read 'as may best be heard of all present.' Each lesson is followed by a canticle or psalm, after the manner of the old responsory, and on the principle that every revelation of the divine character and dealings affords fresh material for His praise.

LEUCORRHOEA (Gr. *leukos*, white, and *rheo*, I flow) is a female disease, in which the most prominent symptom is the discharge of a glairy fluid, often in a considerable quantity. For the special character of this complaint, we must refer to medical treatises; it is sufficient here to say that its general treatment consists in fomentations, the application of emollients, and in the administration of tonics and astringents.

LEUTSCHAU (Hung. *Lőcse*), a town of Hungary, in the county of Zips, 126 miles north-east from Pesth. L. has the oldest Lutheran college in Hungary. The inhabitants, three-eighths of whom are Protestants, are mostly occupied in agricultural pursuits. A peculiar kind of mead made here has a large sale not only in Hungary, but in Poland and Silesia. Pop. 5729.

LEUZE, a town of Belgium, in the province of Hainault, 17 miles north-west from Mons, on the right bank of the Dender, and not many miles from its source. Dyeing, bleaching, brewing, and distilling are actively carried on; also salt-refining and the expressing of oil. Woollen and cotton hosiery and lace are manufactured. Pop. (1863) 6069.

LE VAILLANT, FRANÇOIS, a distinguished traveller and naturalist, particularly eminent as an ornithologist, was born in 1753 at Paramaribo, in Dutch Guiana, where his father, a rich French merchant, was then French consul. When he was ten years of age, his father returned to Europe, and settled at Metz, his native place. Young Le V. received a good education. Beginning as a mere sportsman, he soon became an ornithologist. In 1777, he visited Paris, and inspected the rich collections of natural history there. He was now seized with a strong desire to visit unexplored countries, and embarked, at Amsterdam, in a Dutch vessel for the Cape of Good Hope. Owing to the accidents of war, which had broken out between Britain and Holland, Le V. found himself at the Cape with nothing but his fowling-piece, ten ducats, and the clothes he had on. He found friends, however, in some of the Dutch officials, who assisted him, and provided him with the means of carrying out his intention of South African explorations. He made two principal excursions: the first from December 1781 to April 1782, eastward, at no great distance from the coast, to the Great Fish River, whence he returned by a more northern route through mountainous regions; the second, in 1783 and 1784, northwards from Cape Town as far as the Tropic of Capricorn. In both journeys, his love of adventure was sufficiently gratified, and in the second he endured hardships not inconsiderable.

Finding that his health suffered from fatigue and from the climate, he wisely relinquished further projects of travel, and returned to Europe, taking up his abode in Paris, where he devoted himself to the stuffing of his collection of skins of birds and other animals, an art in which he excelled, and to the preparation of works giving an account of his travels and of his discoveries in natural history. In 1793, during the Reign of Terror, he was thrown into prison, and only escaped the guillotine through the fall of Robespierre. He now retired to a small property at La Noué, near Sezanne, where he chiefly resided during the remainder of his life. He died 22d November 1824, at the age of 71.

Le V.'s chief works are his Travels (*Voyage dans l'Intérieur de l'Afrique*, Paris, 1 vol. 4to, or 2 vols. 8vo, 1790; and *Second Voyage dans l'Intérieur de l'Afrique*, 2 vols. 4to, Paris, 1796), which were speedily translated into English and other languages, and are remarkable for their spirited narration of incident, and the interest with which every subject is invested; and his *Natural History of the Birds of Africa* (6 vols. 4to, Paris, 1796—1812). He published also several works on particular departments of ornithology, as a *Natural History of Parroquets*, a *Natural History of Birds of Paradise*, &c. He made many discoveries in various departments of natural history, but chiefly in ornithology.

LEVICO, a town of the Tyrol, Austrian Empire, nine miles south-east-by-east from Trient (*Trent*), in the upper part of the valley of the Brenta, and near a small lake, the Lake of Levico, from which that river takes its rise. Mulberry trees are cultivated, and the care of the silkworm and spinning of silk give occupation to many of the people. Pop. 5674.

LEYDEN, JOHN, a poet and orientalist of some celebrity, was born at Denholm, a village of Roxburghshire, Scotland, 8th September 1775. His parents were in humble circumstances; but seeing his desire for learning, they made an effort for his education; and after passing through the ordinary course of study in the university of Edinburgh, he was licensed as a preacher or 'probationer' of the Church of Scotland. During the years of his university course, he had, however, learned much that formed no necessary part of it, and in particular, several of the languages of modern Europe, and some of the oriental languages. He was a most ardent and enthusiastic student. His varied gifts and attainments soon recommended him to the attention of some of the most eminent men of the time in Edinburgh. In 1799, his first work issued from the press, *A Historical Account of the Discoveries and Settlements of Europeans in Northern and Western Africa*. About this time also he contributed many translations from the northern and oriental languages, and original poems to the *Edinburgh Magazine*. He contributed to Lewis's *Tales of Wonder*, and aided Scott in amassing materials for his *Minstrelsy of the Scottish Border*. He was editor for one year of the *Scots Magazine*. In order to obtain opportunity of gratifying the strong desire which he felt to visit oriental countries, he studied medicine, and in 1802, sailed for India, having received the appointment of assistant-surgeon on the Madras establishment. Before leaving his native country, he completed his *Scenes of Infancy*, a poem containing much that is beautiful; but on which, however, his reputation does not rest so much as on his minor pieces, and particularly his ballads. After his arrival at Madras, his health soon gave way, and he was compelled to remove to Penang, where he ardently prosecuted the study of the language, literature, history, &c. of the Indo-Chinese tribes. Having resided for a time in

Penang, he left it for Calcutta, on being appointed a Professor in the Bengal College; and he soon afterwards exchanged this office for that of a judge at Calcutta. When the expedition against Java was undertaken, L. obtained leave to accompany the governor-general thither; and at Batavia, in the exploration of a library which contained many Indian manuscripts in its musty recesses, he contracted a fever, of which he died, after a few days' illness, 28th August 1811. L.'s versification is soft and musical; but 'he is an elegant rather than a forcible poet.' His attainments as an orientalist were extraordinary. The chief evidence extant of them, however, is an *Essay on the Languages and Literature of the Indo-Chinese Nations*, published in the 10th volume of the *Asiatic Researches*. His *Poetical Remains* were published in 1819; and a new edition of his *Poems and Ballads*, with Memoir by Sir Walter Scott, in 1858.

LI, the name of a Chinese measure of length. The li = .577 Fr. kilomètre = .358 (rather more than one-third) English mile.

LIBRI-CARRUCCI, GUILLAUME BRUTUS ICLIVS TIMOLEON, COUNT, French mathematician and bibliographer, son of an Italian refugee, who was condemned at Lyon in 1816 for forgery, was born at Florence 2d January 1803. Having early devoted himself to the study of mathematics, he became professor in the university of Pisa, where he contributed to the *Transactions of scientific societies* a number of remarkable papers on *The Theory of Numbers* (1820); *Some Points of Analysis* (1823); *The General Resolution of Indeterminate Equations of the First Degree* (1826); *Some Physical Questions* (1829); &c.

After 1830, having been compromised in the political movements, he was obliged to leave Tuscany, and went to France as refugee. He there found a patron in Arago (whom he afterwards attacked in the most spiteful manner); was naturalised, and in a short time elected Member of the Academy of Sciences, Professor of Analytics at the Sorbonne, Chief Inspector of Public Instruction, and Superintendent of the State Libraries. He was decorated with the Legion of Honour, and appointed editor of the *Journal des Savants*, &c. L.'s works at this period are varied and numerous. In particular may be mentioned his *History of Mathematical Science in Italy from the Renaissance to the End of the 17th Century* (1838—1841, 4 vols. 8vo), in which he displayed much acuteness and erudition. He was, besides, a most determined bibliomaniac, and found means of collecting a library for himself, which contained such a rich stock of *incunabula* of all kinds, and of the greatest typographical curiosities, that several public sales, which he got up for his own benefit, and of which each realised from £4000 to £5000, did not in the least degree diminish his collection. In consequence of the remarkable phenomenon of a library remaining complete in spite of repeated sales, L. began to be suspected of making use of his special position to abstract books and valuable MSS. from the public libraries. A report had even been secretly prepared on the subject by the public procurator, and communicated to M. Guizot to await his decision. The objects abstracted between 1842 and 1847 were approximately valued at £20,000. This document was dated 4th February 1848, and was found in the Foreign Office when the Revolution broke out in that month. The case was immediately taken up by the courts, and after a long and careful examination, the accused, who, in the meantime, had fled to England, was condemned, June 1850, to ten years' imprisonment, to degradation, and the loss of his employments. This process

created a great sensation, and gave rise to an immense deal of writing for and against the condemned. The most important is an article by P. Merimée, *Le Procès Libri*, in the *Revue des Deux Mondes* (1852), for which the writer was imprisoned, as having, in defence of a 'book-stealer,' slandered and insulted the French judicature.

L. continued for two or three years to address letters and pamphlets to persons in France exclaiming against his condemnation in the highest tones of injured innocence. The efforts of M. Merimée in behalf of L., and a petition in his favour, addressed to the senate in 1861, only had the effect of bringing out still more damnatory facts regarding both him and his family.

LIFE MORTARS AND ROCKETS. When a lifeboat is not at hand, or a raging sea and a shoal coast render its use impracticable, a distressed ship may often receive help from shore, provided the distance be not too great for the throwing of a rope. A small rope may draw a thicker, and that a hawser, and the hawser may sustain a slinging apparatus for bringing the crew on shore. For short distances, Captain Ward's *heaving-stick* (fig. 1)

Fig. 1.—Captain Ward's Heaving-stick.

has been found useful: it is a piece of stout cane two feet long, loaded at one end with 2 lbs. of lead, and at the other attached to a thin line. It is whirled round vertically two or three times, and then let go; but it cannot be relied on for more than fifty yards. Kites of various kinds have been employed, but are not found to be certain enough in action. The firing by gunpowder of some kind of missile, with a line or rope attached to it, is the method which has been attended with most success. In 1791, Sergeant Bell, of the Royal Artillery, devised a mode of firing a shot and line from a distressed ship to the shore. It was afterwards found to be more practically useful to fire from the shore to the ship. In 1807, Captain Manby invented his *life-mortar* (see MANBY, in SUPPLEMENT). His mortar was an ordinary 5½-inch 24-pounder cannon, fixed at a certain angle in a thick block of wood. The missile discharged from it was a shot with curved barbs (fig. 2), something like the flukes of an

Fig. 2.—Captain Manby's Life-shot.

anchor, to catch hold of the rigging or bulwarks of a ship. How to fasten the shot to the rope was at first a difficulty: chains were not found to answer; but at length strips of raw hide were found suitable. To assist in discerning the exact position of a distressed ship on a dark night, in order to aim the mortar-rope correctly, Manby used a chemical composition as a firework, which would shine out in brilliant stars when it had risen to a certain height. A third contrivance of his, for replacing the shot by a shell filled with combustibles, in order to produce a light which would render the rope visible to the crew, was not so successful.

Many variations have been made in the line-throwing apparatus. Colonel Boxer has recently substituted a *bolt* (fig. 3), for the shot, with four holes at the end; fuses thrust into these holes shed a

light which marks the passage of the bolt through the air. Trengrove's rocket-apparatus, invented in

Fig. 3.—Colonel Boxer's Life-bolt.

1821, consisted of an ordinary 8-oz. sky-rocket (see ROCKET). Certain practical difficulties, however, affected it, and it did not come much into use. In 1832, Dennett's apparatus was invented. It nearly resembled the old sky-rocket, but with an iron case instead of a paper one, and a pole eight feet long instead of a mere stick: it weighed 23 lbs., was propelled by 9 lbs. of composition, and had a range of 250 yards. A ship's crew having been saved by the aid of this rocket at Bembridge in the Isle of Wight, the Board of Customs caused many of the coastguard stations to be supplied with the apparatus in 1834. Carte's apparatus, brought forward in 1842, depended on the use of a Congreve rocket (see ROCKET) instead of an ordinary sky-rocket. It does not appear that this apparatus was ever adopted by the authorities. Mr Dennett next sought to improve the power of his apparatus, by placing two rockets side by side, attached to the same stick; and it certainly did increase the range to 400 yards; but as the simultaneous and equal action of the rockets could not be always insured, the scheme was abandoned. Colonel Delvigne, of the French army, invented a *life-arrow* (fig. 4), to be fired

Fig. 4.—Colonel Delvigne's Life-arrow.

from an ordinary musket. It is a stick of mahogany, shaped something like a billiard cue; the thicker end presses on the powder; while the thinner end, loaded with lead, is fitted with loops of string; a line or thin rope is attached to the loops, and the thin end of the stick projects beyond the barrel. The jerk, when the arrow or stick is fired, causes the loops to run down the stick to the thick end: this action has an effect like that of a spring, preventing the stick from darting forward so suddenly as to snap the line. The apparatus will send an arrow of 18 oz. to a distance of 80 yards, with a mackerel line attached. Another French contrivance, Tremblay's rocket with a barbed head, has been adopted for the Emperor's yacht; but as it is to be fired from the ship to the shore, it partakes of the same defects as Sergeant Bell's original invention.

The most effective apparatus yet invented is Colonel Boxer's. Finding that Dennett's parallel rockets on one stick do not work well, he succeeded after many trials in a mode of placing two rockets in one tube, one behind the other (fig. 5). The head is

Fig. 5.—Colonel Boxer's Double Rocket (section).

of hard wood; there is a wrought-iron case, with a partition between the two rockets. When fired, the foremost rocket carries the case and the attached line to its maximum distance, and the rearmost rocket then gives these a further impetus. The

LIFE MORTARS AND ROCKETS—LIFE-ROCKET DEPARTMENT.

effect is found to be greater than if the two rockets were placed side by side, and also greater than if the quantity of composition for the two rockets were made up into one of larger size. The rocket is fired from a triangular stand, and is lighted by fuse, port-fire, or percussion-tube; the elevation is determined by a quadrant or some similar instrument.

The lines used with these several projectiles have varied greatly; but the best is found to be Italian hemp, spun loosely. It is very elastic, and when thick enough for the purpose, 500 yards weigh 46 lb. In Boxer's rocket, the line passes through the tail of the stick, then through the head, where it is tied in a knot, with india-rubber washers or buffers to lessen the jerk. The line is carefully wound on a reel, or coiled in a tub, or faked in a box provided with pins ranged round the interior—to enable the line to run out quickly without kinking or entangling. Dennett's faking-box for this purpose is the one now generally adopted.

Life belts, jackets, and buoys of numerous kinds are used, made of cork, inflated india-rubber, &c.; but the apparatus now employed in conjunction with the life-rockets is known by the curious name of *petticoat-breeches*, or more simply, *sling life-buoy*.

Fig. 6.—Lieutenant Kisbee's Sling Life-buoy, or Petticoat-breeches.

It is not strictly either a belt or a buoy, but a garment in which a man may be slung clear out of the water. When a rocket has been fired, and a line has reached the distressed ship, signals are exchanged between the ship and the shore; a thicker rope is pulled over to the ship by means of the line, and a hawser by means of the rope. When all is stretched taut, by fastening to the masts, &c., articles can be slung and drawn to and fro. The petticoat-breeches, invented by Lieutenant Kisbee, consists of a circular cork life-buoy forming the top ring of a pair of canvas breeches; one of these is hauled over from the shore to the ship; a man gets into it, his legs protruding below the breeches, and his arm-pits resting on the buoy; and he is hauled ashore by block-tackle. The crew of a wrecked ship can thus one by one be relieved. To prevent losing the hawser and other apparatus, when the last man has left the ship, an apparatus called a hawser-cutter is used, working in the ship, but worked from the shore.

Fuller details, with numerous illustrations, will be found in the *Engineer* for 1866, in two papers

written by Mr Gray, of the Marine Department of the Board of Trade.

LIFE-ROCKET DEPARTMENT, or rather, that branch of the Marine Department of the Board of Trade which has the management of life-rockets, mortars, lines, buoys, and belts, divides with the National Life-boat Institution the labours connected with the prevention of shipwreck, and the rescue of shipwrecked persons. This has been the arrangement since 1855. Until that year, the life-mortars in use were partly under the control of the Admiralty, partly under the Board of Customs, partly under the institution just named, and partly belonging to private individuals. The Merchant Shipping Act, passed in 1854, and put in force in the following year, placed the whole under a different organisation. Leaving the life-boats (see *LIFE-BOAT*) under the able management of the admirable institution to which most of them belonged, the other matters were intrusted to the Board of Trade, under rules laid down in a general way in the act.

To work out properly the rocket and life-saving system, a topographical organisation is in the first instance adopted. The coasts of the United Kingdom are classified into 59 coastguard divisions or wreck-registrars' districts; and the coastguard inspector of each division or district has control over all the

rockets, mortars, buoys, belts, and lines kept at the various seaside stations in his district. There were at the beginning of 1867 about 265 of these stations; of which 40 were provided with mortars only, 175 with rockets only, and the rest with both mortars and rockets. Most of the mortars are Boxer's improvement on Manby's; and most of the rockets are Boxer's improvement on Dennett's. There are to be no more mortars introduced, as Boxer's rockets are found more effective. The rockets are made at the Royal Laboratory at Woolwich, and are supplied by the War Department to the stations, on requisition from the Board of Trade; as are

likewise mortar-shot and shells, fuses, portfires, signal-lights, gunpowder, &c. At each station is kept a cart, expressly made to contain all the requisites for the rocket-apparatus. The cart is always kept ready packed, to be drawn to any part of the coast most wanted. Eighteen rockets are supplied with each apparatus; and a new supply is obtained before these are exhausted. The main store of apparatus is kept at Woolwich, whence it is sent to 12 dépôts on the coast, and from these dépôts to the stations, by the coastguard cruisers. The rockets saved 3072 lives between 1855 and 1865 inclusive. Simpler apparatus, consisting of life-belts and life-lines, is kept at a much greater number of stations: at the beginning of 1867, these stations were nearly 600 in number, provided with more than 2000 belts, and nearly 2000 lines.

The system is worked by the coastguard, the men being paid so much for periodical drilling, and so much for regular service. There are also Volunteer Rocket Corps established on certain parts of the coast. Special services are rewarded by the Board of Trade with gifts of money, gold and silver and

bronze medals, gold watches and chronometers, telescopes, binocular glasses, sextants and quadrants: these are paid for partly by annual parliamentary grants, and partly out of the Mercantile Marine Fund.

LIGHTING OF BEACONS AND BUOYS AT SEA. Some interesting experiments have recently been made under the direction of Messrs Stevenson of Edinburgh, the engineers to the Commissioners of Northern Light-houses, 'in order to test the practicability of illuminating beacons and buoys by electricity,' the success of which warrants a practical trial, and it is understood this is about to be proceeded with. At various times since the discovery of the electric light by Sir H. Davy in 1813, suggestions have been made pointing out the advantages which might be derived from its use upon light-houses. It has long been plain, indeed, that for a purpose of this kind it had properties which placed it far in advance of all other lights—such as its near approach to sunlight in brightness, its great power of penetrating fogs, and its total independence of atmospheric air, which enables it to be produced in a vacuum or under water. Unfortunately, its production is attended with great trouble; it also requires rare skill to keep it in perfect order, and even where this is at hand, we cannot yet place absolute reliance upon its steadiness. It has nevertheless been in use at Dungeness, in the south of England, since 1862, and at La Hève in France since 1863, and at both places the light may be said to be practically successful. But there are differences of opinion respecting it among light-house authorities, as the reader will find by consulting an interesting parliamentary paper on the subject, dated May 30, 1866. Whether or not the electric light is to be ultimately adopted for properly constructed light-houses, there can be little doubt that for the illumination of beacons, where no light-keeper is to be constantly on the spot, electricity must in some way be employed as the agent to produce the light. As far as can be at present seen, the ordinary Electric Light (q. v.) may be dismissed as unsuitable for beacons. It will at least require to be greatly simplified before it can be used for such a purpose. In the article **INDUCTION OF ELECTRIC CURRENTS** will be found a description of the method of producing sparks by means of an induction coil. These sparks can be made to follow each other so quickly as to appear like a flash surrounded by a luminous haze. This, then, is the kind of light with which, when placed inside some convenient form of optical apparatus (see **LIGHT-HOUSE**), it is now intended to illuminate beacons.

It is probable that several different arrangements of electrical apparatus—all, however, producing the same kind of light—will be tried; but it will suffice to give an idea of their general plan if we explain one of the methods proposed by Mr Thomas Stevenson, by which, with the aid of instruments constructed by Mr Hart of Edinburgh, this flashing light was successfully produced at Newhaven pier in 1866. In this particular experiment, the electric current passed through a wire 800 feet long. Suppose a beacon to be situated at some distance from the shore, as shewn upon the annexed diagram (fig. 1). A galvanic battery, consisting of, say, six Bunsen cells, is placed at B in a house upon the shore. From this, the electrical current is conveyed along a submarine cable to the beacon, and returns by earth-plates at E, E, in the usual manner, to complete the circuit; its course being indicated on the diagram by arrows. The induction coil is placed upon the beacon at C, and properly connected with the conducting wire of the cable, so as to make the current generated by the battery traverse

its primary coil. A wire from each end of its secondary coil is then conveyed to the focus of the optical apparatus, the ends of the two wires being here brought within half-an-inch of each other, and furnished with indestructible points of platinum.

Fig. 1.

The induced or secondary current, in crossing this narrow space, produces the succession of sparks which constitute the light, but as explained under the head **INDUCTION OF ELECTRIC CURRENTS**, it only does so at the moment the current is interrupted or broken. It is consequently necessary to have some means of completing and breaking the galvanic circuit in rapid alternations, so as to produce the flashes in quick succession. The break for this purpose is placed at I, near the battery.

In the experiments already tried, a great deal was found to depend upon the peculiar way the current was broken. None of the breaks in use giving a successful result, Mr Hart devised a new one of an ingenious construction, which produced a more constant and powerful light. Fig. 2 shews

Fig. 2.

this instrument. The difference between it and other mercury or spring breaks lies in the fact, that with them the current is off and on for nearly equal spaces of time; but this one is so contrived that the wire at a is three times longer in the mercury, b, than it is out of it; consequently, the current is three times longer on than it is off, and so allows the soft iron core of the induction coil to be more fully magnetised. The result of this is a secondary current of comparatively high intensity, and of course the production of more brilliant sparks between its two terminals. We may explain, that the moment the wire at a touches the mercury, the current passes, and the moment it is removed the current stops—the direction it takes being indicated in the figure by the arrows. The wire at a alternately dips and rises by the action of an ordinary electro-magnet, EE, turning the crank c; the second bottle of mercury is not used to break contact, but only to continue the current, for which a spring would answer as well.

By the use of more than one induction coil, the light can be materially increased, so that there is

now a certainty of being able to produce it powerful enough to be seen at the distance of a few miles—a result which, when actually in operation, cannot fail to be of incalculable advantage to the mariner. Strong hopes are entertained that some means will be found of succeeding with the induction coil upon the shore instead of on the beacon, in which case there will probably be little difficulty in illuminating buoys as well as beacons. The use of vacuum tubes, as suggested by Mr T. Stevenson, may facilitate this most desirable application of the electric spark. This gentleman has also suggested the employment of electricity to ring bells, so as to give warning to sailors in foggy weather.

LIGHTNING, ACCIDENTS FROM. According to the Twenty-eighth Annual Report of Births, Deaths, and Marriages, which is just published (August 1867), and has reference to the year 1865, it appears that during that year 19 persons were killed in England by lightning: none in London or in the divisions south of the Thames; 2 in the South Midland Division, 3 in the Eastern, 2 in the West Midland, 7 in the North Midland, 1 in Lancashire, and 4 in Yorkshire. All except 3 were men, and chiefly labourers in the open air. In a previous Report, 24 deaths were referred to this cause, and occurred in the following seasons: summer 11, spring 10, autumn 2, and winter 1. Out of 103 deaths from lightning in five years (1852—1856), there were 38 in July, and 22 in August.

A person struck by lightning is more or less stunned and deprived of consciousness for a time, often, no doubt, by mere fright, in which case the effect is transient; but sometimes in consequence of a shock given to the brain, in which latter case there is a certain amount of paralysis of motion and sensation. In a case recorded by Boudin in his *Géographie Médicale*, 1857, a gentleman, who had been struck by lightning, remained for an hour and a quarter apparently devoid of any indication of life; and the paralysis, which usually affects the lower limbs, may last for many months. Mr Holmes, in his article on Accidents from Lightning, in his *System of Surgery*, gives the following list of other affections caused by lightning: 'Burns, more or less extensive; eruptions of erythema or of urticaria, which are said by one author to have re-appeared with each succeeding thunder-storm; loss of hair over parts or the whole of the body; wounds; hæmorrhage from the mouth, nose, or ears; loss of sight, smell, speech, hearing, and taste; or, in rare cases, exaltation of these special senses; cataract; imbecility; abortion.' Another curious effect of lightning is that described under the head of **LIGHTNING-PRINTS**. In reference to the occasional loss of hair, M. Boudin (*op. cit.*) relates that the captain of a French frigate, who was struck by lightning on board his ship, could not shave himself on the following day, the razor not cutting but tearing out his hair. From that day, the beard disappeared, and the hair of the scalp, eyebrows, &c. gradually fell off, leaving him entirely bald. The nails of the fingers also scaled away. Sir B. Brodie tells a curious story of two bullocks, pied white and red, which were struck in different storms: in both cases the white hairs were consumed, while the red ones escaped. As a general rule, it seems that persons not killed on the spot usually recover. The burns present every degree of intensity; in some (probably exaggerated) cases, we hear of men and animals being reduced to ashes, while in ordinary cases they vary from deep burns, difficult in healing, to mere vesications: they must be treated in the ordinary method. It was believed until recently that the burns are caused by the ignition of the clothes; it appears, however, from

various cases collected by Dr Taylor (*Med. Jurisp.*, 1865, p. 737), that burns, at all events in some cases, are the direct result of the electricity. One case is so singular that we shall give a few details regarding it. Mr Fisher of Dudley was called in to see a man who sixteen hours previously had been struck by lightning while milking a cow. The cow was killed on the spot, and the man was much injured, there being a severe burn extending from his right hip to his shoulder, and covering a large portion of the front and side of the body. His mind was wandering; there were symptoms of inflammatory fever, and he was confined to bed for 17 days, at the end of which time the healing process was not complete. On examining his dress, it was found that the right sleeve of his shirt was burned to shreds, but there was no material burning of any other part of his dress. Hence it is obvious that the dress may be burned without the surface of the body being simultaneously injured; and further, that a serious burn may be produced on the body although the clothes covering the part may have escaped combustion.

The appearances after death vary extremely. The body sometimes retains the position which it occupied when struck; while in other cases it may be dashed to a considerable distance. The clothes are often burned or torn, and have a peculiar singed smell; and metallic substances about the person present signs of fusion, while such as are composed of steel become magnetic. There are generally marks of contusion or laceration; or if they are absent, extreme Echyrosis (q. v.) at the spot where the current entered or emerged. In addition to wounds and burns, fractures have also been noticed.

The treatment must be directed to the special symptoms, which are liable to great variations. Sir B. Brodie's advice is as follows: 'Expose the body to a moderate warmth, so as to prevent the loss of animal heat, to which it is always liable when the functions of the brain are suspended or impaired, and inflate the lungs, so as to imitate natural respiration as nearly as possible.' These means should be fully tried, as respiratory action has been restored after more than an hour's suspension. Mr Holmes additionally recommends cold affusion, stimulating enemata, and stimulants by the mouth; and recovery (he states) is apparently hastened by the administration of tonics, especially quinine, and gentle action on the skin by means of baths.

LIMOUX (anc. *Limosum*), a town of France, in the dep. of Aude, in the centre of a fertile valley, on the left bank of the Aude, 52 miles south-east from Toulouse. There are manufactures of fine broadcloths, yarn factories, tanneries, dye-works, &c. The neighbourhood produces a much-esteemed white sparkling wine, known as *Blanquette de Limoux*, which rivals Champagne in excellence. Diligences ply regularly to Toulouse, Carcassonne, and Foix. Pop. (1866) 5913.

LINA'RES, a town of Spain, in the province of Jaen, 24 miles north-north-east from Jaen. The neighbourhood was celebrated in ancient times for its mines of copper and lead, which are still very productive. A fine fountain which adorns the town is supposed to be Roman. Pop. about 6500.

LINCOLN COLLEGE, OXFORD, was founded in 1427 by Richard Fleming, Bishop of Lincoln, for a Rector and 7 Fellows, and afterwards greatly augmented by Thomas Rotherham, Bishop of Lincoln, Archbishop of York, and Lord High Chancellor of England, who added 5 fellowships, and gave a new body of statutes in 1479, in which the election of Fellows was limited to the diocese of Lincoln,

York, and Wells. These limitations were abolished, however, by an act of parliament, 17 and 18 Vict.; and the foundation at present consists of a Rector, 12 Fellows, and 18 Scholars. Of the scholarships, 3 belong to the old, and 1 to the new foundation, 12 were founded by Dr Hutchins, Lord Crewe, Bishop of Durham, and Dr Radford, rectors. The patronage consists of 11 benefices, in the counties of Oxford, Lincoln, Essex, Dorset, and Bucks, of the annual value of £3097. In 1866, this college had 137 members of convocation and 215 members on the books.

LINDSAY, THE FAMILY OF. This Scottish historical House is of Norman extraction. One of the race obtained lands in England from the Conqueror; another, Sir Walter de Lindsay, settling in Scotland under David I, acquired Ercildoun, and Luffness in East Lothian. The descendant of the latter, William Lindsay of Ercildoun, High Justiciary of Lothian in the latter half of the 12th c., acquired the lands of Crawford in Clydesdale, which the family continued to hold till about the close of the 15th century. He married Princess Marjory, sister of King William the Lion, and had three sons. The eldest inherited Crawford; and the descendants of the second were the House of Lamberton, who for a time eclipsed their elder brethren; but the line of both ended in heiresses; and Crawford eventually came to the descendants of William of Luffness, third son of the Justiciary, who, in the 14th c., added largely to their estates by marriage with a coheir of Lord Abernethy. Sir James Lindsay of Crawford was one of the most notable of the Scotch barons engaged in the battle of Otterburn.

EARLS OF CRAWFORD AND DUKE OF MONTROSE.—Sir Alexander Lindsay, younger brother of Sir James of Crawford, the hero of Otterburn, acquired large estates in the counties of Angus and Inverness by marriage with the heiress of Stirling of Glenesk and Edzell; and his son David, who, on failure of the line of his uncle, became chief of the family, married the sister of Robert III., and was raised by that king, in 1398, to the dignity of Earl of Crawford. In the 15th c., the earls of Crawford were among the most powerful of the Scotch nobility: they assumed a regal state, had their heralds, and were attended by pages of noble birth. Their domains were widely extended over Scotland, but their chief seat was Finhaven, in Angus. David, third earl, entered into an alliance, offensive and defensive, with the eighth Earl of Douglas and Macdonald of the Isles, Earl of Ross, and wielded for a time, during James II.'s minority, an authority far exceeding that of royalty. He was slain at Arbroath in a private feud with the Ogilvies. His son, nicknamed 'Beardie,' or the 'Tiger Earl,' renewed the league with Douglas. On James having treacherously stabbed Douglas at an interview at Stirling, he rose in rebellion; and the Earl of Huntly, lieutenant-general of the kingdom, who had aided the Ogilvies at Arbroath, took up arms against him. Earl Beardie was defeated at Brechin, and forfeited; but he was afterwards restored to his lands and dignities, and to royal favour, and entertained James at Finhaven, who flung down a loose stone from the castle battlement in fulfilment of a vow which he had taken to make the highest stone of the castle the lowest. The family attained their climax of power and wealth under David, fifth earl, a faithful friend of James III., and employed by him in his most important foreign embassies, who was made Duke of Montrose in 1488, a title which had never before been bestowed in Scotland but on princes of the blood-royal. On the accession of James IV., an act rescissory was passed of all grants and titles conferred by his predecessor during the

last eight months of his reign; but soon afterwards, a new charter of the dukedom of Montrose was granted on a recital of the duke's good services to the king and his predecessor. David, eighth earl of Crawford, nephew of the Duke of Montrose, had the misfortune to have a son known for his crimes and enormities as 'The Wicked Master'; his conduct led his aged father to consent to a transfer of the earldom to David Lindsay of Edzell, the next heir. The ninth earl, who succeeded under this conveyance, moved with pity for the rightful heir, son of the 'Wicked Master,' obtained a re-conveyance of the earldom to him after his own decease. From that time, the fortunes of the family began to decline. The 12th earl was imprisoned by his relatives as a spendthrift. The 16th earl, a companion in arms of the great Montrose, having no issue, through the influence of a powerful cadet of the family, Lord Lindsay of the Byres, a new patent of the earldom was obtained from Charles I., bringing in his branch of the House before the descendants of the uncle of the 16th earl, who had been created Lord Spynie, or the intermediate cadets of Edzell and Balcarres.

LORD LINDSAY OF THE BYRES, VISCOUNT GARNOCK.—Sir William Lindsay, younger brother of the first Earl of Crawford, acquired extensive estates with his wife, a daughter of Sir William Mure of Abercorn. He was hereditary bailie and seneschal of the regality of the archbishopric of St Andrews, an office which remained in his family till the middle of last century. His grandson was made Lord Lindsay of the Byres, county Haddington, in 1445. The Lords Lindsay of the Byres were sturdy champions of popular rights and of the Presbyterian faith; their principal residence was Struthers Castle in Fifa. The fourth lord endeavoured in vain to dissuade James IV. from his fatal expedition to England in 1513; in consequence of which, James vowed that, on his return, he would hang him on his own gate, a threat, of course, rendered futile by the fatal result of Flodden. The fifth lord was one of the four noblemen to whom the charge of the infant Queen Mary was committed on the death of her father. The sixth lord, the fiercest and most bigoted of the Lords of the Congregation, was deputed by the rest to obtain Mary's compulsory resignation at Lochleven, an office which he is said to have discharged in a severe and repulsive manner; and the seventh lord bearded James VI. in the presence-chamber regarding the changes he was effecting in ecclesiastical polity. The tenth Lord Lindsay of the Byres was in 1644 created Earl of Lindsay; and in virtue of Charles I.'s above-mentioned patent, he became 17th Earl of Crawford, a dignity enjoyed by his descendants till their extinction. He held the offices of High Treasurer of Scotland, and an Extraordinary Lord of Session; and though a warm partisan of the Covenant, he was a loyal and consistent adherent of the Stuarts. In 1648, he entered with zeal into the proposal to raise an army to effect the king's rescue; and in 1657, while forwarding Charles II.'s plan of marching into England, he was arrested, carried to London, and detained a prisoner in the Tower and Windsor Castle. He was released by the Long Parliament in 1660, on the recall of the secluded members, and was reinstated in his offices and dignities at the Restoration. We find him afterwards making a strong effort to dissuade Charles from introducing Episcopacy in Scotland. The Treasurer's grandson by a younger son was created Viscount Garnock in 1703. The fourth Viscount Garnock succeeded as 21st Earl of Crawford; his son, the 22d earl, was the last of the direct line of the Byres; and at his decease in 1808,

the Crawford earldom returned, in terms of the patent of Charles I., to the line of Balcarres, while the Crawford Lindsay estates went to heirs-female. A claim by an alleged descendant of this branch of the House to both peerage and estates, was long a matter of public interest and notoriety: it eventually collapsed from the discovery that the principal documents founded on were ingeniously contrived forgeries.

Sir David Lindsay of the Mount, Lyon King of Arms, the courtly knight, poet, and philosopher, and friend of the Reformation in its earlier stages, was descended from a natural son of the first Sir William Lindsay of the Byres.

EARL OF BALCARRES AND CRAWFORD.—The Lindsays of Balcarres, in Fife, were a branch, and eventually the representatives of the Lindsays of Edzell, who, as already seen, had temporarily possessed the earldom of Crawford on the attainder of the 'Wicked Master.' The first of them was Lord Menmuir, a Lord of Session and Secretary of State to James VI., possessed of accomplishments and cultivation rare in his age. His son David was created Lord Lindsay of Balcarres in 1633, and his grandson, Alexander, Earl of Balcarres, in 1651, in reward of their steady support of the royal cause. The sixth Earl of Balcarres became *de jure* Earl of Crawford on the death of the 22d earl, the last of the Byres line; and that title has been recognised by the House of Lords to belong to his son, James, seventh Earl of Balcarres, and 23d Earl of Crawford, the present representative of the family. The Earl of Crawford has further preferred without success a claim to the dukedom of Montrose, conferred by James III. Alexander William Crawford, Lord Lindsay, eldest son of the Earl of Crawford and Balcarres, holds a high position in literature, and is author of *Sketches of the History of Christian Art*, in 3 vols., a work of considerable value, but uncompleted; and *Lives of the Lindsays*, a family memoir, combining to a rare extent genealogical research with biographical interest, to which reference is made for further particulars regarding the Lindsays.—See also Jervise, *Land of the Lindsays*.

LINGUAGROSSA, a town of Sicily, in the province of Catania, on the north-eastern slope of Mount Etna, 1725 feet above the sea, 37 miles south-west from Messina. It is said to derive its name from the rustic dialect of its inhabitants. Pop. (1861) 7844.

LINGULA, a genus of brachiopodous molluscs, exhibiting the remarkable peculiarity of a long fleshy pedicle supporting a bivalve shell, and passing between the beaks of the valves. They live attached to rocks in the seas of warm climates, particularly of the Indian Archipelago and Polynesia. The genus is interesting, because, although few recent species are known, fossil species are numerous, and are found in the fossiliferous beds of Britain and other countries, the seas of which now produce none of their congeners.

LINOLEUM is, as its name is intended to denote, a peculiar preparation of linseed oil. In 1849, Niclès and Rochelder independently discovered that chloride of sulphur will solidify oil, and render it usable in many new ways. In 1859, M. Perra communicated to the Académie des Sciences the details of a mode of effecting this by mixing and melting the ingredients, and pouring the mixture out in a thin layer. By varying the proportions, the resulting substance assumes varying degrees of consistency. Thus, 100 linseed oil + 25 chloride of sulphur, produces a hard and tough substance; 100 oil + 15 chloride, a supple substance like india-rubber; and 100 oil + 5 chloride, a thick paste

mass. This third kind dissolves well in oil of turpentine. Mr Walton afterwards found that, by the application of heat, linseed oil will become hard without the addition of chloride of sulphur. He conceives that it is not a mere drying, but a real oxidising. Linseed oil, first boiled, is applied as a layer to a surface of wood or glass, then dried; then another layer; and so on till the required thickness is produced. The sheet is then removed, and is found to be very much like india-rubber in elasticity; in fact, the production of a layer by this means is analogous to the smearing of clay-moulds with caoutchouc juice to produce india-rubber, as practised in South America. See **CAOUTCHOUC**. The drying is a little expedited by adding a small portion of oxide of lead. The solid oil is crushed, and worked thoroughly between heated rollers; and, when treated either with shellac or with naphtha, it becomes applicable in various manufacturing forms. The term *Linoleum* properly applies to the hardened or oxidised oil itself, but it is chiefly used as a designation for one of the substances made from or with it, a kind of floor-cloth. When the oxidised oil is rolled into sheets, it becomes a substitute for india-rubber or gutta-percha. When dissolved as a varnish or mastic, and applied to cloth, it is useful for water-proof textiles, felt carpets, carriage-aprons, wagon and cart sheets, nursing-aprons, water-beds, tank-linings, table-covers, &c., according to the mode of treatment. When used as a paint, it is useful for iron, for wood, and for ships' bottoms. When used as a cement, it possesses some of the useful properties of marine glue. When vulcanised or rendered quite hard by heat, it may be filed, planed, turned, carved, and polished like wood, and used for knife and fork handles, mouldings, &c. When brought by certain treatment to the consistency of dough or putty, it may be pressed into embossed moulds for ornamental articles. When used as a grinding-wheel, touched with emery, it becomes a good cutter. Lastly, when mixed with ground cork, pressed on canvas by rollers, the canvas coated at the back with a layer of the same oil in the state of paint, and the upper or principal surface painted and printed, it becomes the *linoleum* floor-cloth, for the production of which a factory has been established at Staines. Dum's patented fabric for similar purposes has no oil in it: it is a mixture of cork-shavings, cotton or wool fibres, and caoutchouc, spread upon a cotton or canvas back, and embossed with patterns; it is a kind of **KAMPULIION** (q. v.).

LIPPSTADT, a town of Prussian Westphalia, on the left bank of the Lippe, 78 miles north-east from Cologne. It is walled and fortified, and has five gates. L. has manufactures of woolens, leather, vinegar, and starch, brandy distilleries, &c. Pop. (1864) 6910.

LIRIA, a town of Spain, in the province of Valencia, and 12 miles north-west from Valencia. The plain in which it stands is luxuriant with vines and olives. On the summit of a hill in the vicinity is the *Collegio de San Miguel*, an ancient and venerable monastic pile. Pop. 8500.

LITTRÉ, MAXIMILIEN PAUL EMILE, a French journalist and philologist, member of the Institute, was born in Paris, 1st February 1801. He distinguished himself in his studies, and obtained various honours at the grand competition. He began the study of medicine, and pursued it so far with distinction; owing, however, to personal circumstances, he did not take the degree of Doctor, nor enter on practice, but gave himself up to researches in philology and in the history of medicine. He prepared

for this by the thorough study of languages and literature, and mastered Greek, Sanscrit, and the principal ancient and modern languages. There were few subjects of human knowledge to which he remained a stranger.

At the same time that L. took an active part in editing various journals and literary collections, he prepared an edition and translation of the Works of Hippocrates (*Œuvres d'Hippocrate*, 1839—1861, 10 vols. 8vo), a publication which, from its first appearance, was judged sufficient to open for him the doors of the Academy of Inscriptions, 22d February 1839.

L., who held democratic opinions, and had distinguished himself among the combatants of July, became afterwards connected with the *National*, and was one of the principal editors of it till 1851. When M. Auguste Comte's new philosophical and social doctrine appeared under the name of Positive Philosophy, L., attracted by the scientific character of the doctrine, took it up with great ardour, and in 1845, wrote a lucid and clever summary of it (*De la Philosophie Positive*), and afterwards defended it in pamphlets and in journal articles. He looked upon the revolution of 1848 as the advent of his opinions; but soon undeceived, he retired from active politics in October 1848, resigning even his duties of municipal councillor of the city of Paris, duties without salary, and the only ones he ever accepted. He had even refused the decoration of the Legion of Honour.

Returning to a life of study, L. continued his researches in medicine, at the same time working ardently at the history of the French language. Already master of the old forms of the French language, he published in the *Revue des Deux Mondes*—to which he has contributed at different times several papers equally ingenious and learned—an article called, The Homeric Poetry and the Ancient French Poetry (*La Poésie Homérique et l'ancienne Poésie Française*, 1st July 1847), which attracted great attention. In it he attempted the translation of the first book of the *Iliad* in the style of the Trouvères.

The Academy of Inscriptions chose him in place of Fauriel (1844), to be one of the commission charged with continuing *L'Histoire Littéraire de France* (The Literary History of France), and he is one of the authors of vols. xxi., xxii., xxiii. In 1854, he was appointed editor of the *Journal des Savants*, and he has since contributed many articles to that collection. L.'s principal work, although the last in date, is his *Dictionnaire de la Langue Française*, containing, in addition to the usual information in French dictionaries, examples of the several meanings of the words, with exact reference to the classical works from which they are taken, besides the history of the usage of each word in documents anterior to the 17th century. Not only are all questions of grammar and lexicography (including etymology—a subject in which French dictionaries have hitherto been singularly deficient) fully discussed, but historical allusions are explained, and numerous details given regarding the arts and sciences, rendering the work a kind of cyclopædia. In preparation for many years, it began to appear in 1863, and the fifteenth livraison or number has already (1867) appeared, coming down to letter K. This splendid work, which promises to be the real *thesaurus* of the French language, so long a desideratum, did not prevent the French Academy in 1863 from rejecting the author, whom M. Dupanloup denounced publicly as holding immoral and impious doctrines. L. has also published an excellent French translation of Strauss's *Life of Jesus* (1839—1840, 2d ed. 1855); a translation of Pliny's

Natural History in the collection of Latin classics by M. Nisard; *Auguste Comte* Stuart Mill (1866); &c. Previous to the appearance of cholera in Paris, he published a paper on that malady (1832); he was one of the principal *collaborateurs* in the new edition of the *Dictionnaire de Médecine*; long contributed to the *Gazette Médicale de Paris*; and in 1837, he and M. Dezeimeris began the medical and surgical journal called *L'Expérience*. We may also notice from his pen—*Histoire de la Langue Française* (1862, 2 vols. 8vo), which is simply a collection of articles on the ancient French language; then, in another series, *Paroles de Philosophie Positive* (1859), and *Auguste Comte et la Philosophie Positive* (1863). He published in 1857 the *Œuvres Complètes d'Armand Carrel*. His last publication is a volume on Medieval Literature (1867), being a collection of articles contributed to periodicals. In July 1867, he began a magazine, with the title of *Philosophie Positive*, which appears once in two months.—M. Sainte-Beuve has published an interesting *Notice sur M. Littré, sa Vie et ses Travaux* (1863).

LIVINGSTON, EDWARD, an American jurist and statesman, was born on 26th May 1764 at Livingston (afterwards Claremont), in the state of New York. He belonged to a family which, for nearly a century, had been of the greatest weight and distinction in the colony. L. was the son of Robert Livingston, judge of the Supreme Court of New York, and the youngest of a very numerous family. After leaving the college of Princeton, he studied law under his brother Robert, eighteen years his senior (see below), and devoted special attention to Roman jurisprudence. On being called to the bar, he soon obtained an extensive practice. He had spent his youth among the founders of American independence, all of whom he had known as visitors of his father, and he at once attained a prominent position. He was elected a member of Congress in 1794; federal attorney and mayor of New York in 1801; and he would probably have been known only as a prosperous lawyer, had not a great misfortune at this period befallen him. L., as federal attorney, was intrusted with the collection of debts to the state recovered by legal proceedings. He had the greatest aversion to accounts, and intrusted this part of his duty to a clerk, a Frenchman, who appropriated the funds to his own purposes. When L. discovered what had happened, he at once ascertained the balance due to the state, handed over his whole property to his creditors, threw up his appointment, and resolved to quit New York. No entreaty on the part of his fellow-citizens could induce him to remain. Louisiana had just been annexed to the United States, thanks to negotiations conducted by his brother at Paris, and he resolved to settle in the new state. He joined the New Orleans bar in 1804, and at once obtained lucrative practice. He had great difficulties to encounter. The business had to be conducted partly in French and Spanish. The law administered was a strange compound of municipal regulations, Spanish and French law, and the Roman law of the civilians. A proposal was made to introduce the common law of England, and this would have been much to the pecuniary advantage of L., but he opposed the scheme in an eloquent and convincing speech to the Louisiana Chambers, and it was decided that the law of the state should remain based upon the civil rather than the common law. In the dispute with England in 1814 and 1815, L. became aide-de-camp and secretary to General Jackson, and attracted much notice by the admirable bulletins he wrote during the campaign. In 1820, he was appointed to draw up a code of civil procedure for Louisiana. It was the simplest

known up to that time, was found to work admirably, and received the warmest approval from Bentham and other jurists. L. was then employed in reducing to system the civil laws of Louisiana. He had to aid him in the task the French and other modern codes, the nomenclature of Scotch law, and a familiar acquaintance with all that is most valuable in English jurisprudence, and the work produced, the 'Civil Code of Louisiana,' is undoubtedly the most successful adaptation of the civil law to the conditions of modern society. It was adopted in Louisiana in 1823, and has since become the law of many other states. L. was then employed to prepare a new criminal code, and in a preliminary treatise he laid down the principles on which he was to proceed. He proposed the abolition of the punishment of death, and a penitentiary system, which at once drew general attention to his labours. His book was reprinted in London, translated into French, and made a sensation all over Europe, and the author received the congratulations of the most eminent publicists and politicians of England, France, and Germany. His code of crimes and punishments was completed, but not adopted without modifications. L. was elected in 1829 member for Louisiana of the American Senate, and in 1831 appointed Secretary of State for Foreign Affairs. Two years later, he went to France as Minister Plenipotentiary to support a demand of a million sterling made by the United States government for indemnity on account of French spoliations, and he succeeded in securing payment. He had married a lady of New Orleans, of French family and education, had been long conversant with the French language, in which he had been accustomed to plead before the courts of New Orleans, and he became intimately acquainted with the leading jurists and politicians of France. He was admitted an associate of the Academy of Moral and Political Sciences, and received the warmest tribute of respect as one of the greatest philosophical lawyers of his time, although his distinction at home had been chiefly won as a careful and painstaking man of business. L. died on 23d May 1836, at his own estate on the Hudson, in consequence of drinking cold water when very hot.—See notices of his life in French by M. Taillandier and by M. Mignet, and a long biography by Mr H. Hunt, with introduction by S. Bancroft.

LIVINGSTON, ROBERT R., brother of the preceding, an eminent lawyer and politician, was born in New York in 1746. He was one of the five members of the committee charged with drawing up the declaration of independence. When the constitution of the state of New York was settled, he was appointed chief judge, a dignity he retained till 1801. He was then sent to Paris as Minister Plenipotentiary to negotiate the cession of Louisiana to the United States, a duty he discharged with rare ability. He enabled Fulton to construct his first steamer, and introduced in America the use of sulphate of lime as a manure, and the merino sheep, and in many other ways distinguished himself as a national benefactor. He died on 26th March 1813.

The Livingstons whose lives have just been recorded, belong to an American family remarkable for hereditary talent and the large number of its members who have distinguished themselves in the United States as eminent men of letters, magistrates, lawyers, and divines. They descend lineally from the fifth Lord Livingston, who was intrusted with the guardianship of Mary, Queen of Scots, and from the Rev. John Livingston, minister of Ancrum, in Teviotdale, the grandson of the nobleman, one of the most distinguished of the Presbyterian divines. John Livingston was born at Kilsyth on the 21st

June 1603, preached with great success in Ireland, and was one of two commissioners sent by the Scotch kirk to Breda, in Holland, to treat with Charles II. Refusing to take the oath of allegiance, he was banished, and, in 1663, went to Holland, where, as pastor of the Scotch kirk at Rotterdam, he spent the last years of his life. He was the author of several works, the best known of which is his autobiography, frequently published.—See Chambers's *Biographical Dictionary of Eminent Scotsmen*. His son Robert was born at Ancrum in 1654, went to Holland when young, and while still a lad, emigrated to America, and settled in the Dutch village of Albany, in the region of the upper Hudson. He married Alida Schuyler, the widow of a Dutch clergyman, and bought from the Indians a vast tract of land on the banks of the river, embracing upwards of 160,000 acres. Robert Livingston, proud of his ancient lineage, had this property erected into the lordship and manor of Livingston, and from it have proceeded the numerous and wide-spreading race who have perpetuated his name, and the lives of many of whom will be found in the American and French biographical dictionaries.

LIXURI, a town of the island of Cephalonia, on the west shore of the Gulf of Argostoli, a long narrow arm of the sea, and 4 miles west-north-west from Argostoli. It is a Greek bishop's see. The surrounding country is very productive of wine and currants, which are brought to L. for exportation, so that it has a considerable trade. Pop. 6000.

LLERENA, a town of Spain, in the province of Badajoz, and 63 miles south-east from Badajoz, near the ridge of the Sierra de Constantina. It is well built, and has some good churches and other public buildings; it is surrounded by walls, which are flanked with towers, and have numerous gates. The inhabitants are mostly employed in agriculture; but there are some manufactures of linen and woollen fabrics, leather, &c. Pop. 6000. Near L. Lord Combermere with his cavalry routed, on April 11, 1812, a French force of 2500 cavalry and 10,000 infantry, the rear-guard of Soult, under Drouot, retiring after the capture of Badajoz.

LLOYD'S BONDS, the name given to a species of securities introduced by Mr John Horatio Lloyd, the eminent barrister, and much employed by railway and other companies, whose power of borrowing money on mortgage or bond is derived from and limited by acts of parliament. A Lloyd's Bond is an admission under seal of a debt being due by the company issuing the bond to the person in whose favour it is executed, with a covenant to pay the sum due at a time fixed, and to pay interest at a certain rate from the time of issue until payment. The covenant is made by the company, their successors and assigns, with the obligee, his executors and administrators; so that a Lloyd's Bond on the face of it is not assignable, and is not, properly speaking, a negotiable instrument. The value of it consists in its converting a simple contract or ordinary debt into a specialty debt, by which the holder gains a preference over ordinary creditors; and in its enabling the holder, armed with this preference, to raise money upon the faith of the debt, either by assigning his interest in it, or by depositing the bond as a security for advances. A valid Lloyd's Bond, as a security, appears to be inferior to a debenture issued under statutory authority in no respect except that its validity can be put in question.

As railway and other companies which have come into existence under parliamentary authority, have no powers except those which parliament has conferred upon them, their power of borrowing is

limited to the amounts, and must be exercised in the manner which parliament has prescribed. By the Act 7 and 8 Vict. c. 85, s. 19, it is declared illegal for them to grant any loan-notes, or other negotiable or assignable instrument, in security of money advanced, except so far as they are authorised by statute. In general, they have statutory authority to borrow only when a certain portion (usually the whole) of their capital has been subscribed, and a certain portion of it has been paid up. And the statute 8 and 9 Vict. c. 16 (The Companies' Clauses Consolidation Act) provides that their power of borrowing must be exercised under the authority of a general meeting. Previous to the introduction of Lloyd's Bonds, these restrictions upon borrowing really limited the liabilities of companies. They were severely felt by companies whose works were being made or being extended; which often were in need of money, which it was impossible or impolitic to raise by means of calls, and whose borrowing powers had not come into operation, or could not conveniently be resorted to. Mr Lloyd relieved such companies from their difficulties, and to a certain extent defeated the intentions of parliament by taking advantage of the fact that companies, if they were prevented from borrowing, were not prohibited from getting into debt in any other way, and granting acknowledgments of their indebtedness in any form except perhaps that of a negotiable instrument. For work done, for goods delivered, for anything except money advanced, the directors of a company might grant admissions of indebtedness; and Mr Lloyd supplied a form in which such admissions would become almost as binding on a company as a statutory debenture, in which they could be sufficiently marketable, in which they could be conveniently granted by directors on account of all the important objects for the sake of which they could desire to borrow to any extent, without the sanction of a general meeting of the shareholders. The only drawback upon the usefulness (for their purpose) of Lloyd's Bonds has been, that they have only been negotiable at high rates of discount; but this has not prevented companies from using them, in many cases to a dangerous extent. There are instances in which lines have been, for the most part, made by means of Lloyd's Bonds; and they have constantly been used simply as a colourable means of eluding the statutory restrictions upon borrowing. On the other hand, they have been of considerable service to companies in the first period of their existence; and that, on the whole, they are thought to have been useful may perhaps be inferred from the legislature, in framing the Railway Securities Act of 1866 (29 and 30 Vict. c. 103), not adopting the recommendation made in 1864 by a committee of the House of Lords, that nothing should be recovered upon these securities out of the proceeds of the traffic of an embarrassed company until the claims of debenture-holders had been satisfied.

It results, from what has been stated, that a Lloyd's Bond cannot be granted for money lent, but can be granted for any other antecedent debt. It cannot be granted for money lent, though the money has actually been used in paying off debts for which bonds might have been granted. The bond should state the origin of the debt on account of which it is granted, but this is not essential. The courts will in no case assume that a Lloyd's Bond has been issued in breach of statutory provisions; but evidence of an intention to defeat such provisions will invalidate a bond. If there have been no actual debt (as may happen, when a company's accounts with a contractor are unsettled), the instrument will not create one; and in that case, the obligee or holder will not be able to recover, even

though the obligee *bonâ fide* believed that a debt existed; but it is for the company to prove that the debt did not exist. A Lloyd's Bond must be duly sealed with the seal of the company issuing it, by order of the directors, given at a meeting of the directors attended by a quorum. Directors are not personally responsible upon a Lloyd's Bond improperly issued. The leading case upon this subject is that of *Chambers v. The Manchester and Milford-Haven Railway Company* (5 Best and Smith's Rep., 538), decided by the Court of Queen's Bench in June 1864. The form of this instrument (which must be duly stamped) is as follows: 'The A. and B. Railway Company do hereby acknowledge that they stand indebted to C. D. in the sum of £1000 for money due and owing from the said Company to the said C. D., in respect of work and labour done for the said Company by the said C. D. And the said Company for themselves, their successors and assigns, hereby covenant with the said C. D., his executors and administrators, to pay to him, his executors, administrators, and assigns, the said sum of £1000 upon the 1st day of May 1869, and also interest thereon at the rate of 5 per cent. per annum from the date hereof until payment; such interest to be payable half-yearly, on the 1st day of January and the 1st day of July in each year.—Given under the common seal of the said Company, the 1st day of May 1866.—X. Y., Secretary.'

LLUMAYOR, or LLUCH-MAYOR, a town of the island of Majorca, in an inland situation, among mountains, 15 miles south-east from Palma. It has manufactures of linen and woollen fabrica. Wine and brandy are also produced. Pop. 7000.

LÖBAU, a town of Saxony, 40 miles east of Dresden. Near it are mineral springs and bathing establishments. It has tanneries, mills, and bleach-fields. In the ancient *Rathhaus*, the deputies of the six towns of Lusatia met from 1310 to 1814. Pop. (1864) 5022.

LOBOS ISLANDS, two small groups of rocky islands on the coast of Fern, famous for the great quantity of guano which they produce. The southern point of the northern group, *Lobos de Tierra*, is in S. lat. 6° 29'; the southern group, *Lobos de Afuera*, is 25 miles further south. The northern group is about 12 miles from the mainland. The principal island of this group is about 5 miles long, and two miles broad. The southern group consists chiefly of two islands, separated by a narrow channel, the largest being about two miles long.

LODZ (Russ. *Lodsi*), a town of Poland, in the government of Warsaw, and 75 miles south-west from Warsaw. It is situated in a level fertile country, on a small feeder of the Ner, a branch of the Vistula. After Warsaw itself, L. is the largest town in Poland, and is remarkable for the activity with which different branches of industry are prosecuted, particularly the manufacture of cloth and other woollen stuffs. There is also a considerable trade, which is likely to be much promoted by a branch railway, opened in 1865, connecting L. with the great Warsaw and Vienna line. The inhabitants of L. are mostly Germans, or of German origin. Its pop. has of late increased with great rapidity. At the beginning of the 19th c., the town had only a few hundred inhabitants; in 1854, the pop. had increased to 23,302; in 1860, to 31,564; and in 1866, it was estimated as near 35,000.

LOLL BAZAAR, an inconsiderable town of Northern India, in the district of Cush Behar, between the rivers Durlah and Tista, in N. lat. 26° 4', and E. long. 89° 18'. It partly occupies the site of the ruined city of Komotapur, a 'most stupendous monument of rude labour,' the walls of

which were 19 miles in circumference in the inside of the inner ditch. Massive ruins are still to be seen.

LONGTON, a town of Staffordshire, England, in the district of the Potteries, and included in the parliamentary borough of Stoke-upon-Trent. It is about two miles south-east from Stoke, on a small stream, which falls into the Trent, and is on the line of the North Staffordshire Railway. Part of the town is known as **LANE-END**. The growth of the town has been rapid, and is entirely due to the manufacture of china and earthenware, in which the inhabitants are chiefly employed. Pop. (1861) 16,690.

LOULÉ, a town of Portugal, in the province of Algarve, six miles north-by-west from Faro, and 130 miles south-east from Lisbon. It is pleasantly situated on a hill amidst groves of cork trees and pomegranates. The remains of a Moorish castle form a conspicuous feature in the scene. L. is one of the most thriving places in Portugal, and has more than doubled its population within the last forty years. Baskets of aloë-thread are a principal article of manufacture. Pop. (1863) 12,156.

LOVER, SAMUEL, artist, novelist, song-writer, and composer, was the son of a stockbroker in Dublin, and was born in that city in 1797. At an early age, he shewed a great desire to become an artist, and with genius and perseverance, succeeded so far that, in 1828, he was elected a member of the Royal Hibernian Society of Arts. In 1833, he exhibited at the Royal Academy a portrait of Paganini, which is said to have brought him some reputation as a portrait-painter. As a miniature-painter, in Dublin, he took likenesses of the principal aristocracy and leaders of Irish society. But while thus engaged, he discovered that he possessed a genius for authorship as well as for art, and was encouraged to make some attempts in that direction by the favourable opinion of Thomas Moore. In 1832, he published a collection of short pieces, entitled *Legends and Stories of Ireland, by Samuel Lover, R.H.A., with six Etchings by the Author* (12mo, Dublin), which was favourably received, and followed by a Second Series, published in London in 1834. In 1837, Mr L. settled in London, and having made authorship his profession, contributed largely to the periodical literature of the day. He also wrote *Rory O'More*, a romance of Irish life, which immediately became popular. Its production on the stage, with the excellent acting of Power in the principal character, made the author still more known. His next publication was *Handy Andy*, commenced, but not completed, in *Bentley's Miscellany*; the entire work, with illustrations by the author, appearing in 1842. In 1844, Mr L. published *Treasure Trove, the first of a series of Accounts of Irish Heirs, &c.; with twenty-six Illustrations on Steel by the Author*. This was originally published in numbers, under the title of *L. S. D., or Accounts of Irish Heirs, &c.* As a writer of songs, Mr L. holds a well-earned reputation: his *Rory O'More*, *Molly Bawn*, *Low-backed Car*, *Molly Carew*, and others, have long been established favourites with the public. In 1839, Mr L. published a collection of his *Songs and Ballads*, with the words only; but considerably more than 100 of his songs have been separately published with music, composed or adapted by the author himself. In 1844, Mr L. projected an entertainment called 'Irish Evenings,' which was very popular both in London and the provinces. Its success encouraged him to visit the United States, where his entertainment was also well received. He returned from America in 1848, when he made his experiences there the

material for a new entertainment, which he gave in London. Mr L. was for some years in the receipt of a pension from the crown, in recognition of his literary merits. Besides the works already mentioned, and his numerous songs, Mr L. was author of *Metrical Tales, and other Poems*, published in 1860. He was also the editor of a well-selected compilation of songs and ballads, by various authors, entitled *The Lyrics of Ireland*, published in 1858. He died 6th July 1868.

LOW ARCHIPELAGO, or **PAUMOTA ISLANDS**, a very extensive group of small coral islands, lying to the eastward of the Society Islands, and southward from the Marquesas Islands. This group or archipelago extends from 15°—25° S. lat. and from 134°—148° W. long. The navigation of this part of the ocean is, as may readily be supposed, dangerous. Some of the islands are in minor groups, others are quite solitary. The whole pop. is estimated at about 10,000.

LOWE, RIGHT HON. ROBERT, English politician, born 1811, at the rectory of Bingham, Notts, of which parish his father, the Rev. Robert Lowe, was rector. He was educated at Winchester, and University College, Oxford, where he was first-class in Classics, and second-class in Mathematics, in 1833. He remained at Oxford, was elected Fellow of Magdalen in 1835, devoted himself to tuition, and obtained the reputation of being one of the best private tutors in the university. In 1836, he married, and gave up his fellowship. He was called to the bar, by the Honourable Society of Lincoln's Inn, in 1842, and went to Australia to push his fortune. He soon attained a lucrative practice at the Sydney bar, and at the same time threw himself into the party and political struggles of the colony, inveighing loudly against the administrative abuses of the colonial government. In 1843, he was nominated one of the Legislative Council; and in 1845, was elected member for Sydney. He devoted much time and thought to the land question, and also to the question of education. He obtained a committee, and carried a report in favour of the Irish National System, which eventually formed the basis of the educational plan adopted in Australia. He also obtained some credit as a law-reformer. Some successful land speculations put him in possession of a moderate competency; and he returned to England, in 1850, with the design of entering upon a parliamentary career. In 1852, he contested the borough of Kidderminster as an independent member with Conservative tendencies. In 1853, he took office under Lord Aberdeen, as Secretary to the Board of Control, but went out with that government. He opposed the government of Lord Palmerston upon the Turkish Loan Bill, but soon afterwards (August 1855) accepted from that nobleman the post of Vice-president of the Board of Trade. Next session, he brought in, on the part of the government, bills for amending the law of partnership, and regulating the local dues upon shipping; but the Conservative benches opposed his legislative measures with so much pertinacity and success, that the Prime Minister, to save the government from defeat, threw his colleague over, and insisted upon the withdrawal of his measures. At the general election in March 1857, he was invited to offer himself for Manchester. A requisition was signed in a day or two by 4000 electors, and he would have been brought in without the expense of a penny. Feeling himself disqualified, by his tastes and by the style of his oratory, from representing a large constituency, he refused the invitation, and went to Kidderminster. Here he became unpopular with

the working-classes, a riot occurred, and personal violence was inflicted upon him. He gained his seat; but in May 1859, he gladly exchanged his turbulent constituency for the borough of Calne, where the influence of the Marquis of Lansdowne procured his return, and which borough he still represents. In June 1859, he became virtual Minister for Education in Lord Palmerston's second administration. In this office he excited the same amount of personal antagonism. His Education minutes were almost unanimously reprobated by the schoolmasters, clergy, and trustees of schools, and obtained no countervailing support from any other quarter. He retained this office, however, until April 1864, when the House of Commons, on the motion of Lord Cranborne, then Lord R. Cecil, having condemned an alleged practice of the Privy Council Office in tampering with the reports of the Education inspectors, L. resigned office. The Premier offered a Select Committee, and in vain endeavoured to persuade L. to recall his resignation, and await the inquiry. He regarded the question as one of personal honour, and somewhat unnecessarily, as it was thought, left the ministry. His emancipation from the restraints of office exhibited Mr L. in a new phase. No speaker, during the session of 1865, was so logical, so original, and so daring. Challenging Mr Gladstone's implied doctrine of an inherent right on the part of the working-classes to a share in the government, he delivered an able and powerful apology for the existing constitution. One passage in his speech, which was interpreted as imputing venality, ignorance, and drunkenness to the lower classes of the constituencies generally, and protesting against the further reduction of the franchise, led to much denunciation and recrimination. During the recess, L. was appointed, by the government of Earl Russell, a member of the Royal Commission for discovering the nature of the Cattle Plague, and its remedy. On the introduction of the Whig Reform Bill in 1866, L. delivered the first of a series of powerful speeches, which largely contributed to insure its rejection. He was, with other members of what was called the party of 'Adullamites,' offered a poet in the Derby government, but declined to leave the Liberal party, from which he feelingly described himself as a political outcast. When the Derby government, in 1867, attempted to deal with the reform question, L., in a series of speeches, vindicated his consistency as an opponent of all reduction of the suffrage. Circumstances had, however, changed, and the successful opponent of the Whig measure found himself almost alone in protesting against a far more democratic measure of household suffrage. His proposal for the protection of minorities, by permitting, in certain cases, the accumulation of votes on a single candidate, was rejected in the House of Commons; but it was grafted on the Reform Bill in the House of Lords, and their amendment was afterwards accepted by the Lower House. L.'s oratory is deficient in passionate eloquence and depth of humour; but in acuteness, in felicity of illustration, spontaneously flowing from redundant knowledge, and in cogency of argument, he is almost unequalled among the public speakers of his day. His elocution is rapid, and his manner nervous and embarrassed, owing to the want of early oratorical training; but his great intellectual power always commands the attention and admiration of the House of Commons. He still (1868) sits and votes with the Liberal party upon ordinary occasions.

LÜDENSCHIED, a town of Prussian Westphalia, 33 miles north-east from Cologne, in a mountainous district, not far from the right bank of the Volme, a branch of the Rhine. It has cotton-

mills, and manufactures of cutlery, buttons, files, and other articles of hardware. There are calamine mines in the neighbourhood. It has of late increased rapidly in population and prosperity. Pop. (1864) 6216.

LU'GO, a town of Central Italy, in the province of Ravenna, 32 miles south-east from Ferrara. It is supposed to be the site of the ancient *Lucus Diana*. L. is an important provincial town. There is an annual fair which lasts from the 1st to the 19th of September, and is the occasion of a great concourse. L. has a very considerable trade in hemp, flax, rice, wine, brandy, &c. Pop. (1861) 8232.

LU'GOS, a market-town of the Austrian Empire, in the Banat, on the Temeş, a branch of the Danube, 32 miles east-south-east from Temeswar. It consists, strictly speaking, of two contiguous towns, the inhabitants of the one, *DEUTSCH-L.*, being mostly of German race, and those of the other, *ROUMANISCH-L.*, or *WALLACHISCH-L.*, being Roumanian. The pop. of the former is 2435, and of the latter 7950.

LUNAWAURA, a small state of India, under British protection, in the Rewa Canitta division of Guzerat. It is situated on the confines of Guzerat, and is a continuation of the mountain tract which forms the extreme north-east of that province. The capital, from which the state derives its name, is 160 miles north-west from Indore, on the left bank of the Mahi, or Myhee, a river which flows into the Gulf of Cambay, and is in N. lat. 23° 8', E. long. 73° 37'. It is a fortified town, the fortifications and town together being about three miles in circumference; and is a place of considerable trade and activity. The state is about 900 sq. m. in area.

LUNDY ISLE, an island of Devonshire, England, in the mouth of the Bristol Channel. It is about three miles in length from north to south, and one mile in breadth, having an area of 1800 acres. Its south point is about 12 miles from Hartland Point, on the coast of Devonshire, and its north end about 29 miles from St Gowan's Head, in Wales. Its shores are rocky and precipitous, and approach to them is rendered dangerous by numerous detached or insular rocks. There is only one landing-place, which is on the south side, and near it are dangerous reefs and insulated rocks. The pop. in 1861 was 48. Near the southern end of the island is a light-house, on a height 567 feet above the sea. At an early date, this island is said to have belonged to a family named Morisco, one of whom having conspired against the life of Henry III., fled hither, and became a pirate. L. I. was the scene of a remarkable occurrence in the reign of William and Mary. A party of Frenchmen landed from a ship of war under Dutch colours, on pretence of desiring to bury one of the crew in consecrated ground, the coffin being really filled with arms, with which the party armed themselves in the church, having requested the islanders to leave them alone to their own funeral rites, and issuing forth, they desolated the island, hamstringing the horses and bullocks, flinging the sheep and goats over the cliffs, and stripping the inhabitants even of their clothes. The cliffs of L. I. are the resort of multitudes of gannets, or solan geese. Granite is the rock chiefly prevailing in the island, but slate appears at its south end.

LUTE (Ger. *Laut*, sound), an obsolete stringed musical instrument, which has been superseded by the harp and guitar. It consisted of a table of fir; a body or belly, composed of 9 (sometimes 10) convex ribs of fir or cedar; a neck, or finger-board, of hard wood, on which were 9 (or 10) frets, stops, or divisions, marked with catgut strings; a head, or cross, on which were placed the pegs or screws that tightened or relaxed the strings in tuning; and a

bridge, to which the strings were attached at one end, the other end being fastened to a piece of ivory, between the head and neck. The number of strings, originally 6, of which 5 were doubled, so as to make 11, was gradually increased till they numbered 24. The performer used his left hand to press the stops, and struck the strings with his right. A peculiar description of notation, called *tablature*, was employed in music written for the lute. The strings were represented by parallel lines, on which were placed letters of the alphabet, referring to the frets: thus, A marked that the string was to be struck open (or without pressing any of the stops); B, that the first stop was to be pressed; C, the second, and so on: while over the letters were placed hooked marks, corresponding to the minim, crotchet, quaver, &c., to indicate time. So carelessly and inaccurately was lute-music generally written, that it is no easy matter to render it into the ordinary notation. The lute was formerly in high favour all over Europe as a chamber-instrument; and it was used in dramatic music to accompany the recitative. In the time of Handel, there was a lute in the Italian Opera in London; and there was a lutanist in the King's Chapel down to the middle of last century.—For a minute account of the lute, and how to play it, see *Mace's Musick's Monument* (Lond. 1676).

LÜTTRINGHAUSEN, a prosperous manufacturing town of Rhenish Prussia, 18 miles south-east from Düsseldorf. Woollen, linen, and cotton manufactures are carried on; also manufactures of hardware and cutlery. Pop. (1864) 8920.

LU'ZULA, a genus of plants of the natural order *Juncææ*, differing from rushes in having a 3-seeded instead of a many-seeded capsule, and in having soft plane leaves, which are generally covered with thinly-scattered longish hairs. They do not grow in wet places, like rushes, but in woods, pastures, and elevated mountainous situations. The English name, **WOOD-RUSH**, has sometimes been given to the whole genus, but is only appropriate to some, of which it is the popular name, as *L. sylvatica* and *L. pilosa*, common British species. Perhaps there is

no more common British plant than the **FIELD-RUSH** (*L. campestris*), a plant of very humble growth; the flowering spikes of which, congregated into a close head, their dark colour relieved by the

Wood-rush (*Luzula sylvatica*): a, a flower.

whitish yellow of the anthers, profusely adorn dry pastures in spring. It is of little agricultural value. The species which grow under the shade of trees are valuable, as preserving their verdure in winter, adding to the beauty of the scene, and improving the cover for game.

M

MACARSCA, or **MARKASKA**, a town of the Austrian Empire, in Dalmatia, on a small bay of the Adriatic, near the mouth of the Narenta, and 34 miles south-east from Spalatro. The plague carried off half the inhabitants in 1815 and 1816, and the place has not yet completely recovered its prosperity. It carries on some trade, but the greater number of the inhabitants are employed in agriculture and fishing. Pop. 7386.

MACCALUBE, an interesting mud-volcano or air-volcano of Sicily, situated not far from the road between Girgenti and Aragona. It is known to have been in a state of frequent activity for the last 15 centuries. It consists of a large truncated cone of barren argillaceous earth, elevated about 200 feet above the surrounding plain, with wide cracks in all directions, and numerous little hillocks with craters, which at times emit a hollow rumbling noise, and throw up a fine cold mud mixed with water, a little

petroleum and sulphureous gas. Reports like the discharge of artillery are occasionally heard; slight local earthquakes are felt, and mud and stones are thrown up to a height of thirty feet or more.

MACFARREN, **GEORGE ALEXANDER**, an English musical composer and essayist of high reputation, son of George Macfarren, a dramatic author and musician. He was born in London, March 2, 1813, and his education was conducted at the Royal Academy of Music, at which institution he became a Professor in 1834. As an operatic composer, Mr M. is the most characteristic representative of the national English school—his aim being to revive the old English music in modern opera. His earliest dramatic work, *The Devil's Opera*, was produced in 1838; *Don Quixote* followed in 1846; and *King Charles II.* in 1849, which first brought out Miss Louisa Pyne in English opera. A cantata, *The Sleeper Awakened*, was brought out at the National Concerts in 1850, *Lenore* in 1852, *May-day* in 1856, and *Christmas* in 1860. The opera of *Robin Hood* followed in the same year, which attained a

popularity far beyond its predecessors, and was performed during a whole season to overflowing houses. The *opera di camera* of *Jessy Lea* followed in 1863; *She Swoops to Conquer* and *Helvellyn* in 1864. Mr M.'s works comprise numerous other small dramatic pieces, as well as chamber music, vocal and instrumental, and several symphonies and overtures. He has also contributed largely to the literature of music as a critic and essayist. His *Rudiments of Harmony*, published in 1840, now stands in high repute. In consequence of the divergence of that work from some of the prevailing views on the subject, he was obliged to resign his professorship in the Academy of Music, in which office, however, he was unconditionally reinstated in 1851.

MACLURE, SIR ROBERT JOHN LE MESURIER, the discoverer of the North-west Passage, was born at Wexford in January 1807, and was sent for his education first to Eton, and afterwards to Sandhurst. Intended for the military profession, but having no great love for it, he secretly left Sandhurst, and through the good offices of a friend, was entered as a midshipman on board the *Victory*. He volunteered for the Arctic Expedition in H.M.S. *Terror*, Captain Back, in 1836. In this expedition, which returned to England, after great hardships, in the autumn of 1837, Mr M. was rated as second-mate. In November 1837, he received his commission as a lieutenant; and in February 1838, was appointed to the *Hastings*, 74 guns, sitting at Plymouth; on the 16th June of the same year, to the *Niagara*, 20 guns, on the lakes of Canada; on the 17th August, as first-lieutenant to the *Pilot*, 16 guns, on the North American and West Indian station; and on the 18th June 1842, to the command of the *Romney* receiving-ship at the Havana, where he remained until the early part of 1846. After this, he was employed for some time in the coastguard service. In 1848, he joined Sir James Ross's expedition in search of Franklin; and upon its return in 1849, he was promoted to the rank of Commander. This expedition had barely returned to England when it was resolved by the Admiralty to despatch the vessels composing it, viz, the *Enterprise* and the *Investigator*, on a fresh search for the Franklin party by way of Behring's Strait. Accordingly, Captain Richard Collinson, C.B., was appointed as senior officer to the *Enterprise*, and Commander M. to the *Investigator*. On the 20th of January 1850, the vessels set sail, with instructions to make the best of their way to Cape Virgins, in order to arrive at Behring's Strait in July. The *Investigator* could not keep up with the *Enterprise*, which was towed through the Strait of Magellan by a steamer, some time before the *Investigator* got there. After rounding Cape Horn, the *Investigator* met with her consort lying at anchor in Fortescue Bay; but soon again they separated, and met no more during the voyage. Captain M. now proceeded alone, in the *Investigator*, towards the ice-regions. On the 2d of August, after passing through Behring's Strait, he spied, in lat. 72° N., ice right ahead. On the 8th, his men first met with Esquimaux, close to Point Pitt, where a party was sent ashore to erect a cairn, and place a notice of the *Investigator* having passed. These Esquimaux encouraged them in the belief that, as they proceeded eastward, they would find an open channel. As they proceeded, however, along the coast of America, the ice became troublesome, and even threatening. There were also numerous shoals, which made the navigation intricate and dangerous. On the 14th August, the *Investigator*, after one or two narrow escapes, found herself quite beset with these shoals, and at last grounded; but after about five hours, again got free, not without the loss of a boatful of provisions. On the 31st of August, the *Investigator*

reached Cape Bathurst, from which she continued to advance for several days in a north-easterly direction. On the 11th September, unmistakable signs of winter presented themselves. On the 16th, the *Investigator* was still advancing towards Barrow Strait, and on the following day, she reached her most advanced position in lat. 73° 10' N., and long. 117° 10' W., about 30 miles from the waters of that series of straits called Melville, Barrow, and Lancaster, communicating with Baffin's Bay. The ice now almost hemmed the vessel in on every side; and it was debated by Captain M. and his officers whether to return, or winter, at all hazards, in their present position. The latter was the course adopted. During the next fortnight, the *Investigator* drifted slowly first backwards, and then forwards, until eventually she became fixed in the ice, in lat. 72° 50' N., and long. 117° 55' W. The woollen housing was now spread over the vessel, and the curtains nailed down to the gunwale upon the northern side of the vessel, to shield the men from the cutting blasts of that quarter. Captain M. and his officers also set themselves to devise means for the amusement and employment of the crew. All were in good health and spirits, notwithstanding the gloomy prospect of a long winter in such a region. Rambles on the ice became frequent; and on the 22d October, Captain M. determined to reach the sea, if possible, by a sledge-journey. He accordingly set out with a party of men and officers; and after sustaining much fatigue and privation, was at last rewarded, on the 26th, by a sight of the North-west Passage. The position of Mount Observation, from which the important discovery had been made, was ascertained to be in lat. (observed) 73° 30' 39" N., long. 114° 39' W., and by lunar 114° 14' W.' After this discovery, the party returned to the *Investigator*; but that vessel was not destined herself to sail homewards through the passage discovered by her commander. All that winter and spring, she remained frozen up in the ice. In July, she began to move again, but the nearest she could get to the passage was 73° 43' 43" N. lat., and long. 115° 32' 30", 25 miles from the waters of Barrow Strait. This was on August 15, 1851. On the following day, Commander M. resolved to abandon this course, go round the south end of Banks' Land, and endeavour, by passing to the westward of it, to reach Melville Island by that route. For 300 miles and more, the *Investigator* sailed in this direction, without being once checked by ice. On August 19, however, a sudden change came; the ice pressed against both sides of the vessel, and immense masses threatened to topple over, and sink her with their weight. By September 1, the *Investigator* became completely ice-bound about 50 yards from the shore. On the 10th, however, there was another change; the ice broke from the coast, carrying the *Investigator* with it, and she slowly sailed along for several days, until eventually she settled in a bay, where Commander M. resolved to winter. To this bay he gave the name of Bay of Mercy, in gratitude for the escape of the ship and crew from numerous dangers, as also because the neighbouring land abounded in reindeer, hares, and other animals, which gave them good supply of food. In this bay, they passed their second Christmas, and the time wore on until April 1852, when Commander M. visited Melville Island with a sledge-party, in the hope of finding some of Captain Austin's ships, or at least a dépôt of provisions; but was disappointed. He returned to the vessel, where all were still well; but in May, the scurvy broke out among his crew, and increased during the summer. August came, and still there was no open channel, and in the following month, it became clear that they must pass a third winter in the ice.

MACROOM—MAESHOWE

It now became necessary to decide what they should do for the future, as provisions were failing; and accordingly, Commander M. announced to his men that, in the following April, he would send away 30 of the crew to make their way homewards in two parties—one by way of North America up the Mackenzie River; the other by way of Cape Spencer, Beechey Island; while he himself, with the remainder of the officers and crew, would stay by the ship, spend a fourth winter, and then, if not relieved, endeavour to retreat upon Lancaster Sound. The men cheerfully acquiesced; and when April came, the sledges were got ready for the retreating parties. On the 6th of that month, Commander M. and his first-lieutenant were walking near the ship conversing, when they perceived a figure rapidly approaching them from the rough ice at the entrance of the bay. When within a hundred yards of them, he shouted and gesticulated, but without enabling them to guess who it could be. At length, he came up to them, and to their joy and astonishment, announced himself thus: 'I am Lieutenant Pim, late of the *Herald*, and now in the *Resolute*. Captain Kellett is in her at Dealy Island.' Pim had

come from Melville Island, in consequence of one of Captain Kellett's parties having discovered an inscription left by Commander M. on Parry's famous sandstone rock in Winter Harbour. Commander M. now resolved, although reluctantly, to abandon his ship altogether, and return with Captain Kellett to England. He reached England on September 28, 1854. His first reward was to receive his commission of Post-captain, dated back to the day of his discovery of the North-west Passage. Shortly afterwards, he received from her Majesty the honour of knighthood. A reward of £10,000 was also granted to the officers and crew of the *Investigator*, as a token of national approbation of the men who had discovered a North-west Passage from the Pacific to the Atlantic Ocean. In March 1856, Sir Robert M. was appointed to the command of H.M. steam-corvette *Esk*, serving in the East Indies and China, but which returned to England in 1861.

MACROOM, a post and market town of the county of Cork, Ireland, situated on the river Sullane, 21 miles west from Cork, with which it is connected by railway. The pop. in 1861 was 3289. The town consists merely of a single street, nearly a mile long, and contains some good houses and shops, but the great majority of the dwellings are mean and poverty-stricken.

MAD-APPLE, a name sometimes given to the Apple of Sodom (*Solanum Sodomense*), sometimes to the fruit of the Egg-plant (q. v.), and sometimes to the large Galls (q. v.) known as *Mecca* or *Bussorah Galls*, and which are also called Apples of Sodom.

MAESHOWE, an artificial mound with an interior chamber, of unknown antiquity, situated on the mainland of Orkney, about nine miles in a westerly direction from Kirkwall, and little more than a mile from the famed Standing Stones of

Fig. 1.—Maeshowe: Exterior View.

Stennis. M. is described as follows by a recent visitor (W. Chambers) in *My Holidays*, a privately circulated work (1867): 'It is situated in an open

Fig. 2.—Maeshowe: Ground-plan.

heathy spot; outwardly, there is little to be seen—only a circular grassy tumulus, or barrow, as it is called by antiquaries, measuring 36 feet high, and about 92 feet in diameter at the base, at which a low door presents itself. Made aware of

Fig. 3.—Runes, interior of Maeshowe.

our errand, a girl from the neighbouring farmhouse arrives with the key of the door, a couple of candles, and a box of lucifer-matches. We have also bits of candles with us; and with the whole lighted, we enter the aperture, crouching as we advance along

a passage varying from a width of 2 feet 4 inches at the entrance, to 3 feet 4 inches at the opening into the interior chamber. The height, low at first, expands to 4 feet 8 inches. The passage is formed by slabs of stone, above, below, and along the sides. On issuing into the central chamber, our candles at first feebly enable us to comprehend its dimensions. These we at length discover. We are in a vault built of slabs of stone, measuring 15 feet square, except at the corners where there are buttresses. The height is 13 feet. On each of the sides, except that with the entrance, at a height of 3 feet from the floor, there is a square opening to a cell or recess, the largest of which is 7 feet in length by 4 feet 6 inches in breadth. The roof of the vault had originally been constructed with slabs advancing successively layer above layer to the centre; but as a result of recent repairs, when the structure was cleared out and restored to something like its former condition, the roof is now partly composed of arched masonry, with an aperture for ventilation. As can be easily supposed, this strange subterranean chamber is cold and clammy. The slabs of stone are wet with damp, and nothing induces a protracted stay but the wish to examine certain Runic inscriptions and emblematic or fanciful figures carved on a few of the stones. These carvings were discovered only at the opening and repairing the chamber, an operation undertaken at the instance of Mr James Farrer, M.P., a learned and enthusiastic antiquary. In a privately circulated work on Maeshowe, by Mr Farrer, and also in a work by Mr J. M. Mitchell, the carvings have been explained partly through the assistance of Norwegian scholars. All refer to Vikings and other Scandinavian heroes, or to transactions in the middle ages. Fig. 3 represents one of these inscriptions. According to Mr Farrer's interpretation, it signifies: "Molf Kolbainson carved these Runes to Ghaut"—Ghaut being possibly a comrade who fell in battle. Mr Mitchell's translation runs thus: "Tholfe Kobainson cut these Runes (on) this cave." Such is a pretty fair specimen of the interpretations of the different inscriptions; scarcely two persons agreeing in the signification. [We have reason to believe that the diversity here referred to arises from the fact that imperfect transcriptions of the Runes had been submitted to the foreign scholars who acted as interpreters. We are sorry to learn that damp is likely soon to deface these interesting inscriptions.] Several purport to refer to hidden treasure, a circumstance which throws a degree of ridicule over the whole, for no one carves inscriptions on stones telling the world where money is secretly deposited. Of the emblematic or fanciful figures, nothing can be made. One is a figure of a horse with an animal like an otter in its mouth, a second is a winged dragon, and a third is a worm knot. These figures may represent the names of ships, or may be whimsicalities signifying nothing.

"There is nothing in these Runes to explain the origin or use of the structure. We are left to conjecture that it was erected as a sepulchral vault in extremely remote times; and being opened by Scandinavian rovers, in the hope of discovering hidden treasure, they used it as a resort or hiding-place, and carved the inscriptions which still remain to attest their visits. Obviously, the building and the passage communicating with it were erected on the open plain, and then covered with the earth which forms the tumulus. There is at some distance an enviroing mound and ditch, still pretty entire. The whole structure bears a resemblance to the vaulted tumuli in other parts of the British Islands. In one at Newgrange, on the banks of the Boyne, near Drogheda, the walls are composed of

tall blocks set on end; whereas, at Maeshowe, the slabs are built one above another (without mortar), as in an ordinary wall. This general resemblance points to a common origin. We have yet to learn, however, why this part of Orkney should be so rich in memorials of an extreme antiquity.'—For a very minute account of M., we refer to a paper by Mr John Stuart, Secretary of the Society of Scottish Antiquaries, circulated as a pamphlet, 1867.

MA'GDALA, a town of Abyssinia, about 120 miles south-east from Gondar, on the left bank of the Bahilo, a feeder of the Blue Nile, at an elevation of about 9000 feet above the level of the sea, and within a few miles of the mountains of the Falla country, the peaks of which are covered with snow for nine months of the year. M. is a small town, having a pop. of only 3000 or 4000, but has recently acquired note as the place of residence of the Negus or king of Abyssinia, and as the place of captivity of the British prisoners, for whose rescue an expedition was at last sent out, in 1867, by the British government. As a fortress, it is regarded by the Abyssinians as impregnable. Its castle, or *amba*, is a rock-fortress, completely surrounded by a wall of columnar basalt, which varies in height from 30 to 700 feet. Art has been employed to add to its strength. The length of the *ambas* is about three-fourths of a mile, and its breadth from 500 to 800 yards. It contains the king's houses, a church, the treasury, the jail, several large open spaces, and a number of groups of soldiers' huts. The garrison is said, in a letter from one of the captives, dated 31st August 1867, to amount to about 1200 men.

MAGNESIUM AND THE MAGNESIUM LIGHT. Although the discovery of the metal magnesium was made by Sir H. Davy in 1808, it was looked upon as little more than a chemical curiosity for about half a century. In 1830, a French chemist, Bussy, obtained globules of the metal by fusing globules of potassium, in a glass tube, with anhydrous chloride of magnesium. Bussy's labours were followed by somewhat improved methods, adopted by Bunsen, and subsequently by Matthiessen, who succeeded in pressing some grains of the metal into wire. The first great advance on Bussy's labours was in 1856, when Deville and Caron effected the reduction of the pure chloride of magnesium by mixing it with fused chloride of sodium in clay crucibles, using fluoride of calcium as a flux, and throwing in fragments of sodium; they thus obtained magnesium on a larger scale than any of their predecessors. The most important part of their investigations was the discovery of the volatility of the metal. All these were, however, mere laboratory experiments. In 1859, Bunsen of Heidelberg, and Roscoe (now of Manchester), published a Memoir on the great importance of magnesium for photographic purposes, owing to the high refrangibility and the great actinic power of the light emitted by burning magnesium-wire. The study of this Memoir led Mr Sonstadt to consider whether, the magnesian salts being so abundant, the metal might not be obtained, on a comparatively large scale, at a moderate price. After a prolonged series of expensive experiments, he succeeded, in 1862, in producing specimens of the metal, varying from the size of a pin's head to that of a hen's egg. Although it burned freely enough, it was still wanting in ductility and malleability, in consequence of the presence of certain impurities; but by May 1863, these difficulties were overcome by a process of purification by distillation; and by the close of that year, he considered it safe to begin manufacturing. The Magnesium Metal Company was

MAGNESIUM AND THE MAGNESIUM LIGHT.

consequently organised, and operations commenced at Manchester. One great advantage of his method is its simplicity: it can be accomplished by the hands of ordinary workmen ignorant of all chemical knowledge. The process of manufacture may be thus described: 1. An anhydrous chloride of magnesium is prepared by saturating lumps of rock-magnesia (carbonate of magnesia) with hydrochloric acid, and then evaporating the solution to dryness. 2. One part of metallic sodium cut in small pieces is placed in an iron crucible, and covered with five parts of the chloride. The crucible is covered, and heated to redness, when the chlorine leaves the magnesium, and unites with the sodium, for which it has a stronger affinity. When the crucible has cooled, and its contents are removed *en masse*, and broken, the magnesium—in that state known as crude magnesium—is seen in nuggets of various sizes, varying from granules to masses as large as a hen's egg. 3. The distillation of the crude metal is effected in a crucible through which a tube ascends to within an inch of the lid. The tube opens at the bottom into an iron box, placed beneath the bars of the furnace, where, on the completion of the operation, magnesium is found in the form of a heap of drippings, which may be melted and cast into ingots or any desired form. The difficulty of obtaining a metal with so little ductility in the form of wire—the only form that was originally used for yielding light—had still to be overcome; and after various partially successful attempts to press small quantities into wire by Matthiessen and others, Mr Mather of Salford devised a piece of machinery by which the metal is pressed into wire of various thickness. Mr Mather also was the first who obtained the metal in ribbons, in which form, from the larger exposed surface, combustion takes place more completely. To the same gentleman is also due the credit of having constructed the first magnesium lamp, in which the end of the wire or ribbon is presented to the flame of a spirit-lamp. As the wire or ribbon consumed, it was paid off by hand from a reel, and propelled between rollers through a tube which conducted it to the flame. A concave reflector diffused the light forwards, and protected the eyes of the operator.

The first time that a photograph was ever taken by this light was at Manchester in the spring of 1864 by Mr Brothers and Dr Roscoe. That the magnesium light, in a more or less modified form, must prove of extreme value to photography, cannot be called in question. Besides overcoming the obstacle of unsuitable weather for the employment of sunlight, it may be applied both for the exploration and the photography of various dim structures, underground regions, &c., such as the interior of the Pyramids, of catacombs, natural caverns, &c., which could not otherwise be examined or photographed. Professor Piazzi Smyth, the Scottish Astronomer-royal, dating from the East Tomb, Great Pyramid, February 2, 1865, writes as follows: 'With any number of wax-candles which we have yet taken into either the King's Chamber or the Grand Gallery, the impression left on the mind is merely seeing the candles, and whatever is very close to them, so that you have small idea whether you are in a palace or a cottage; but burn a triple strand of magnesium wire, and in a moment you see the whole apartment, and appreciate the grandeur of its size and the beauty of its proportions.' According to the writer of an excellent article in the *Technologist* for 1865, 'M. Madar is said to be engaged on a series of photographs of the Catacombs of Paris; various artists are busy practising on monuments in obscure recesses of continental churches; and Mr Brothers, we believe, contemplates undertaking the

caves of Derbyshire.' For portraiture, it is found to be less successful than was at first expected, owing to the intense light within a few feet of the sitters's eyes causing a contraction of the facial muscles.

One of the peculiarities of the magnesium light is, that it displays colours as they are seen in sunshine. This may be tested, and a very interesting effect produced, by burning some wire in a garden or conservatory at night. This peculiarity is being turned to practical account. The magnesium lamp, says a writer in the *British Journal of Photography*, promises quickly to become a regular article of furniture in every silk-mercer's show-room. 'The strength of the magnesium light, coupled with its easy production, qualifies it for extensive employment in commerce and war. Unlike the electric and oxyhydrogen lights, it involves no cumbersome and troublesome apparatus. With a coil of the wire in his waistcoat pocket, and a few matches, an Alpine explorer has instant means for making his whereabouts known at night. The light has been seen at a distance of twenty-eight miles at sea; how much further, remains to be determined. Commissions under several governments are investigating its capabilities, and there is reason to believe that it will very soon be adopted for ship-signals and light-houses.'—*Technologist*, *op. cit.* In surgery, the light has been successfully employed in connection with the laryngoscope; and by this means not only can the slightest sore in the upper part of the respiratory organs be discovered, but the same may be rendered visible to a numerous audience. How far the magnesium light can be applied to the ordinary purposes of illuminating streets, public buildings, &c., is not yet determined. The objectors to such applications of the light maintain that, while light in which carbon constitutes the ignitable solid possesses a power of diffusibility which renders objects not directly opposed to the course of the rays more or less distinctly visible, the electric, lime, and magnesium lights possess none of this diffusiveness; their rays being apparently projected with a force and velocity which deprive them of the power of diffusion. An object placed in the direct course of the rays is splendidly illuminated, and the rays are projected to an immense distance; but the shadows cast by intervening objects are intensely black, and the rays seem to pass through the atmosphere without producing much effect, except upon that part which is in the course of the stream of light. 'And herein,' observes Mr Willmitt, who does not adopt these objections, 'would appear to reside the supposed cause of failure of the application of this light to ordinary illumination.'—*Pharm. Journ.* for April 1865.

It is found by experiment that $2\frac{1}{2}$ oz. of magnesium wire will give out as much light as 20 lbs. of the best stearine candles, and at this rate, the magnesium light is not much dearer than that of the best candles. Mr Grant, the well-known photographer, has ascertained that certain alloys into which magnesium enters largely, afford nearly as brilliant a light as pure magnesium, with various tinges of colour; thus, one part of zinc and two of magnesium produce an alloy which burns with a slightly blue tinge; one part of copper and three of magnesium give a green light; while one part of strontium and two of magnesium give a red light. Such modifications of the light may prove highly serviceable in signalling, besides being much less expensive in most cases than the pure light.

Various forms of the magnesium lamp have been devised, the best of which is Larkins's Magnesium Powder-lamp, in which arrangement a mixture of finely divided sand and powdered magnesium is

projected in a graduated stream, and is submitted to combustion, in place of a wire or ribbon of the pure metal. It is simple in construction, small in size, and very portable; and the light is continuous, and quite under control. It is easily ignited, and as easily extinguished; and as the magnesium is burned in powder, all clock-work, &c. is dispensed with. Amongst the advantages of the light, in addition to its intensity, may be mentioned—(1) that it gives off no compounds unpleasant or injurious to man or his surroundings, such as plate, fur, paper-hangings, books, &c.; (2) that it is altogether unattended with danger from explosion, the whole chemical process involved being a union of the metal with the oxygen of the air, and the only result being oxide of magnesium or magnesia; and (3) the portability of the materials.

The great drawback to the more general application of this light is its price, but this difficulty will doubtless be soon overcome. In the *Year-book of Facts in Science and Art*, 1867, p. 173, it is stated that 'one year ago its price was 112 guineas per lb.; now (1866) magnesium wire is sold at 3d. per foot.' The expense of the working of Larkins's Lamp is one pound per hour. When the metal can be obtained more cheaply (the sodium necessary for its reduction being the great expense), it and its alloys will probably be found serviceable in the construction of household vessels, cases, light and simple machinery, &c.; and it has even been suggested in the *American Gas-light Journal* that when it becomes cheap enough, it should be employed in the construction of vessels of war, for, whilst little heavier than oak, it is as strong and tenacious as steel.

From information directly obtained from the London agents of the Magnesium Metal Company (Mears Johnson, Matthey, & Co., Hatton Garden), we learn that the present wholesale price of the pure metal, in the form of wire or ribbon, of the ordinary sizes for burning, is 10s. per oz.; and in the form of plates, ingots, or powder, is 7s. 6d. per oz., while the crude metal sells at 5s. per oz. The respective retail prices are 12s., 9s., and 6s. per oz. It may also be mentioned that the present wholesale price of pure sodium, on which the expense of the magnesium solely depends, is 6s. per lb. Any quantity of wire or metal less than one ounce is sold at the rate of 16s. per oz.; and as the ordinary series of wire run from 80 to 200 feet per oz., and those of ribbon from 80 to 150 feet per oz., a very simple calculation gives the present price of the wire per foot.

MAGNETO-ELECTRIC MACHINE (Wilde's). See ELECTRIC LIGHT; MAGNETISM. Mr H. Wilde of Manchester has lately (1866) patented a magneto-electric machine, which, with a sufficient expenditure of mechanical energy, can be made to furnish any amount of current electricity. It accomplishes this with a simplicity and economy hitherto unequalled, and it promises thereby to extend immensely the practical importance of electric science.

The machine is founded on a new and somewhat paradoxical principle—viz., that a *current or a magnet indefinitely weak can be made to induce a current or a magnet of indefinite strength*. A general description will best shew how this is proved and applied.

Fig. 1 shows a front elevation of a 7-inch machine, constructed for the Commissioners of Northern Light-houses. It consists of two separate machines—a purely magneto-electric machine, and a machine which is both electro-magnetic and magneto-electric. Both machines are in the main very similar, and in many respects identical, the only difference being in

size and power. The smaller machine, MM', which is purely magneto-electric, is seen surmounting the other. The horse-shoe permanent magnet, MM', is the foremost of a series of sixteen similar magnets, placed the one behind the other in a horizontal row. Each weighs 3 lbs., and sustains a weight of 20 lbs. The sixteen magnets are fixed below to the

Fig. 1.

magnet-cylinder, c, shewn on a larger scale in fig. 2. This is partly made up of cast-iron, partly of brass. The two iron components, i, i (fig. 2), form the sides of it, and the brass bars, b, b, lie between them. They are bolted firmly together by the brass bolts, r, r. The magnet-cylinder is about 12 inches in length; in the centre of it is accurately bored a circular hole, extending the whole way, 2½ inches in diameter. The inner side surfaces of the magnets below are accurately fitted to the upright plane sides of the magnet-cylinder, and are firmly secured to it. By this means the cast-iron portions of the magnet-cylinder, i, i, form the polar terminations of the magnetic battery, the brass bars, b, b, between them, breaking the magnetic continuity.

A cylindrical armature, aa, of cast-iron is made to revolve within the magnet-cylinder. Its diameter is 1/8th of an inch less than the diameter of the cylinder, which enables it to revolve without

MAGNETO-ELECTRIC MACHINE.

friction in very close proximity to the polar surfaces. The manner in which it is centered is, for the sake of simplicity, not shown in the upper

Fig. 2.

machine, but it is shown in the lower machine, where, as is afterwards mentioned, the construction, though larger, is perfectly similar. The framework for sustaining the axis of the armature is firmly bolted at *gg*. Fig. 2 gives, as just mentioned, an enlarged cross section; fig. 3 shows an enlarged side-view.

Fig. 3.

half revolution.
622

Two rectangular grooves, *w*, *l*, are made on opposite sides, giving to it somewhat the appearance of a rail. About 50 feet of insulated copper-wire, *ww*, is wound lengthwise into these grooves in three coils (shown in section, fig. 2). The coil thus formed is shut in by wooden packing, *W*. In fig. 3, this packing is removed from the two ends, to show the longitudinal winding of the coil. To prevent the wires from being driven out by the centrifugal force generated in the rapid rotation of the armature, straps of sheet-brass encircle the armature at regular intervals, and are sunk in grooves prepared for them in the cast-iron. Two caps of brass, *k*, *k*, are fitted to the ends of the armature, and to these are attached the steel journals or axes of rotation, *j*, *j*. On the further axis (the back axis of fig. 1), the pulley, *m*, is fixed, round which passes the strap from the steam-engine which works the machine. On the other axis (the front axis of the figure), two rings are put, one, *n*, insulated from it, and the other, *n'*, connected with it. One end of the armature coil is in connection with the armature, and thereby with the axis and *n'*; the other end is insulated and fixed by a binding-screw with *n-n* and *n'* are thus the terminals of the coil. They are made of hardened steel, and the springs, *s* and *s'*, which press against them are of the same material.

Starting from the position shown in fig. 2, the armature in one revolution induces two opposite currents in the coil, one in the first, the other in the second. It will be seen (fig. 3) that the

separation between *n* and *n'* lies obliquely. In this way, each spring, *s* or *s'*, presses against a different ring at each half-revolution. As *n* and *n'* change their electric sign it is so arranged that they change the spring, *s* or *s'*, against which they press. Thus, *s* and *s'* receive their currents always in the same direction; consequently, the wires, *o* and *o'*, convey the current away from the machine in a uniform direction. The armature is made to revolve 2500 times per minute, and 5000 waves or currents of electricity are transmitted to the wires, *o*, *o'*.

Thus far we have nothing essentially peculiar in Wilde's machine. The construction of the magnet-cylinder is quite novel, though the position of the armature, which is decidedly the most advantageous, is not new, as it was adopted several years ago in Siemens and Halske's magneto-electric machine. One advantage of this position lies in the motion of the armature not being resisted by the air. In the ordinary position of the armature, much of the work applied to the rotation is expended in the armature beating the air. There is no such loss in Siemens and Halske's or Wilde's machine. Another advantage is derived from the inductive action of the magnet being exerted directly on the coil, as well as through the intervention of the armature. If the coil were made to rotate without the armature, currents would be induced in it of the same kind as that induced by the armature, though of feebler intensity, the maximum points of which would occur when the coil was moving through the line joining the poles, and the minimum points when it was at right angles to that position. Now these are the converse of the maximum and minimum induction points of the armature. In the position in which the armature is placed in this machine, both armature and coil contribute to the current, the one most when the other gives least, and *vice versa*. The same advantage is not secured by the ordinary construction.

We come now to describe the singular peculiarity and merit of Wilde's machine. The current got from the magneto-electric machine is not directly made use of, but is employed to generate an electro-magnet some hundreds of times more powerful than the magnetic battery originally employed, by means of which a corresponding increase of electricity may be obtained. This electro-magnet, *EE'* (fig. 1) forms the lower part of the figure, and by far the most bulky portion of the entire machine. It is of the horse-shoe form, *E* and *E'* forming the two limbs of it. The core of each of these, shown by the dotted lines, is formed by a plate of rolled iron, 36 inches in height, 26 inches in length, and 1 inch in thickness. Each is surrounded by a coil of insulated copper-wire (No. 10), 1650 feet long, wound round lengthwise in seven layers. The current has thus, in passing from the insulated binding-screw, *r*, to the similar screw *r'*, to make a circuit of 3300 feet. Each limb of the electro-magnet is thus a flat reel of covered wire wrapped round a sheet of iron, the rounded ends alone of which are seen in the figure. The upright iron plates are joined above by a bridge, *P*, built up also of iron-plate, and are fixed below the whole way along with the iron bars *u*, *v* to the sides of a magnet-cylinder of precisely the same construction as the one already described. The iron framework of the electro-magnet is shown by the dotted lines. The depth of the bridge is the same as the breadth of the bars, *u*, *u'*, which are of the same size as the bars, *v*, *v*. The various surfaces of juncture in the framework are planed, so as to insure perfect metallic contact. The upper and lower machine are in action precisely alike, only the upper magnet is a permanent magnet, and the lower one an electro-magnet. We have the same magnet-

cylinder, I, I, the same armature, A, and springs, S, S', and the same poles, Z, Z'; the size is, however, different: the calibre of the magnet-cylinder is 7 inches. The diameter of the lower armature gives the name to the machine—viz., a 7-inch machine. Figs. 2 and 3 are on the scale of the lower machine (fig. 1). The length of wire on the lower armature is 350 feet. It is 35 inches in length, and is made to rotate 1800 times a minute. The cross framework attached at *gg* to the magnet-cylinder, in which the front journal, *f*, of the armature rotates (at *Q*), is shown in the lower machine (fig. 1). When the machine is in action, both armatures are driven simultaneously by belts from the same countershaft. For the electric light, the currents conveyed to the springs, S and S', need not be sent in the same direction. In that case, the separation between *n* and *n'* is vertical; and each spring presses against only one ring during the whole revolution, receiving and transmitting each revolution two opposite currents. Oil for the journal and commutator is supplied from the cup C.

The machine here described is intended for a three-horse power steam-engine, but more power might be expended on it. A larger engine could drive the smaller armature faster, and thereby cause much more energy to be expended, and more electricity to be induced in turning the lower armature than with the power of three horses. The machine, when worked with a power of three horses, will consume carbon-sticks three-eighths of an inch square, and evolve a light of surpassing brilliancy. With a machine that consumes carbons half an inch square, a light of such intensity is got, that when put on a lofty building it casts shadows from the flames of street-lamps a quarter of a mile distant upon the neighbouring walls. The same light at two feet from the reflector darkened ordinary sensitised photographic paper as much in twenty seconds as the direct rays of the sun at noon on a clear day in March in one minute.

Mr Wilde furnishes for the electro-magnet cylinder of many of his machines two armatures: one an 'intensity armature,' similar to that just described; the other a 'quantity armature'—one of which may be easily substituted for the other. The quantity armature, instead of insulated copper-wire, is enveloped in folds of insulated copper-plate, or ribbon, which offering little resistance, a current of much greater quantity, though of less tension, is given off. It is with the quantity armature that experiments in the heating-power of the machine are best performed. With a 10-inch quantity armature, Mr Wilde succeeded in melting an iron rod 15 inches long and $\frac{1}{4}$ inch thick.

Wilde's machine enables us to convert any amount of mechanical energy into electricity. By increasing the size of the electro-magnet, or by using a second electro-magnet, induced by the first, an unlimited amount of energy can be expended, and so converted. The size and weight of the apparatus is also small. The entire machine just described is under 5 feet in length and height, is 20 inches wide, and weighs a ton and a half. Mr Wilde also contemplates making a smaller machine, useful for lectures and institutions, to be worked with the hand, which will form a ready and convenient substitute for the galvanic battery in electric experiments.

Mr Wilde attributes the power of his machine to the power that an electro-magnet has, of accumulating and retaining a charge of electricity in a manner analogous to, but not identical with, that in which it is retained by the Leyden jar. The polar terminals, for instance, of a very large electro-magnet can be made to give a bright spark 25 seconds

after all connection with the exciting magneto-electric machine has been broken.

Wilde's machine forms quite an era in the history of electro-magnetic machines. It is not only marvellous in itself, but it is also equally so in the investigations to which it has given rise. Wheatstone and Siemens have found that the magnetic battery (MM', fig. 1) may be dispensed with, and they charge the electro-magnet, EE', by the current coming from the lower revolving-armature, A. If the electro-magnet, EE', be once charged, as much residual magnetism is left as will serve for all time coming. The amount of this is insignificant, but it is utilised in the following way. When the armature begins to revolve, it does so very easily, almost as if there were no magnetism to impede it. The feeble current, however, thus generated goes to strengthen the magnetism of the electro-magnet. The increment of magnetism thus produced acts in its turn on the armature, causing it to revolve with greater difficulty, and to give off, in consequence, a stronger current. This mutual reaction between the electro-magnet and the armature goes on increasing; and if sufficient mechanical force be exerted to turn the armature, a current of such strength would be induced as would melt the wires of the coils, and destroy the instrument. Wilde's principle, that a small amount of magnetism can produce a current of any strength, however great, thus receives a new and startling verification, and one which he did not anticipate. It may be asked, however, what practical result are we to expect of a machine that generates and consumes its own current, seeing that, in the machines of Wheatstone and Siemens, the current of the armature is taken up by the electro-magnet? The armature-current may have, however, a divided circuit between its poles; one of these being formed by the electro-magnet coils, and the other by any external passage offered to it—the current being apportioned to each inversely as the resistance each route offers. Or, the external circuit may be periodically closed, in which case an instantaneous current of great strength passes through it, made up of the proportional part of the armature-current and of the accumulated electricity of the electro-magnet, the latter being the larger constituent.

The reaction principle of the Wheatstone and Siemens is also employed in Ladd's beautiful electro-magnetic machine, at present the greatest novelty of its kind. In this instrument, the revolving-armature is furnished with two coils, one at each end, each provided with its own commutator. One of these coils furnishes the current that charges the electro-magnet, and the other gives a current available for external use. The former of these coils supplies the place of the upper armature of Wilde's machine. Ladd's machine has therefore the advantage in point of simplicity. So far as it has been tried, it gives excellent results. Wilde's machine is the only one as yet that has been tried on a large scale, and its performances for the present stand unrivalled.

MAHIM, a town of the island of Bombay, and seven miles north of the city of Bombay, to which it is joined by railway. It is situated on the south side of the channel separating the island from Salsette, and at the point where they are connected by a road running partly on arches of masonry, partly on a causeway. The passage is commanded by a fort. The town is ill built, and inhabited chiefly by Christians of Portuguese descent, who have here a church and some other relics of their former prosperity. The inhabitants are chiefly employed in fishing, the place being famous for its oysters. Pop. 9000.

MAITLAND, a town of New South Wales, in the county of Northumberland, on the Hunter river, 93 miles north of Sydney, and 20 miles north-west of Newcastle, to which it is joined by railway. It is divided by the river into East and West Maitland. Pop. of the former (1861), 1834; of the latter, 5694. The former has one or two churches, a court-house, and jail; the latter, which is the most thriving place, has several churches and schools, numerous large stores and hotels, and an extensive manufacture of tobacco. Good coal abounds in the neighbourhood. Along with Newcastle, M. returns a member to the legislative assembly.

MA'LDAAH, a town of British India, in the presidency of Bengal, the chief town of a district of the same name, is situated on the left bank of the Mahanunda, about 190 miles north of Calcutta. In the rainy season, it is nearly insulated. It is a wretched place, consisting of ruined houses, forming narrow irregular streets, full of filth. The surrounding district has become a melancholy desert from want of cultivation. Pop. estimated at about 15,000.

MALLET, **CLAUDE FRANÇOIS DE**, born 28th June 1754, at Dôle in Franche-Comté, became an eager supporter of the Revolution, rose to the rank of a brigadier-general in 1799, was intrusted with the government of Pavia in 1805, but was removed from his office because of his extreme republicanism. He returned to Paris, and was engaged in a number of republican plots. Being, in June 1812, thrown into confinement along with some royalists, he formed with them a scheme for overthrowing the empire during Napoleon's campaign in Russia. He made his escape from prison on the night of 23d—24th October, along with the Abbé Lafon, and entering the barracks, informed the soldiers that the tyrant had perished in Russia. He proceeded to liberate Generals Guidal and Lahorie from prison; and having previously gained the support of a battalion of the Parisian Guards, he called them to arms, and went to the residence of Hullin, the commandant of the city, whilst Lafon went with a platoon to the prefecture. He told Hullin of the death of the Emperor, and the establishment of a provisional government, and on his manifesting doubt, drew a pistol and fired it in his face, wounding but not killing him; whereupon the adjutant, Laborde, rushing in, Hullin and he together overpowered M., and took him prisoner. When interrogated, he declared that he would have made all France and all Europe his debtors, if his enterprise had been successful, and maintained the same resolute coolness to the last. He was shot, along with his principal fellow-conspirators, 29th October 1812.

MANAGUA, a town of Central America, in the state of Nicaragua, in a healthy and fertile district, on the south shore of Lake Managua or Leon, 50 miles south-east of Leon. The town is the seat of the government of Nicaragua, and has a pop. of 10,000, chiefly Indians. Owing chiefly to the rivalries of the cities of Granada and Leon, but partly also to its central position, M. has been selected as the place of meeting of the legislative chambers.

MANBY, **GEORGE WILLIAM**, favourably known for his exertions in saving the lives of persons in danger of shipwreck, was born in 1765, at Hilgay, near Downham Market in Suffolk. After studying for the army, he served seven years in the militia. Receiving the appointment of barrack-master at Yarmouth in 1803, he had frequent opportunities of witnessing the ravages produced by storms on the coast of Norfolk and Suffolk. A dreadful series of shipwrecks on a particular day in 1807, when H.M. gun-brig *Saize* was wrecked within 60 yards of the

shore, and 67 lives lost, and when 147 dead bodies were found on about 30 miles of coast, drew his attention forcibly to the subject; and led him to experiments which resulted in the invention of the apparatus known by his name (see **LIFE MORTARS AND ROCKETS** in SUPPLEMENT). On February 12, 1808, he succeeded in saving the lives of the crew of the brig *Elizabeth*, which was stranded at 150 yards from the shore; he sent a rope over to them by means of a shot, and this rope was the means of pulling a boat from the shore to the brig. A career of usefulness was thus commenced, which he followed for the remaining 46 years of his life. In 1810, a committee of the House of Commons voted £2000 to M., as a token of recognition of his services. Being appointed to report on the dangers of the Norfolk and Suffolk coasts, he recommended the establishment of mortar-stations at certain intervals. This recommendation was adopted by the House of Commons and the government; and by the year 1815, there were nearly 60 such stations. Captain M. received a further grant from parliament in 1823 of £5000; to which were added honorary distinctions from many foreign governments. It was estimated that, by the time of his death, nearly 1000 persons had been rescued from stranded ships by means of his apparatus. He wrote two works on his favourite subject, *An Essay on the Preservation of Shipwrecked Persons, with a descriptive account of the Apparatus, &c.* (1812); and *Practical Observations on the Preservation of Mariners from Stranded Vessels, and the Prevention of Shipwreck* (1827). In what manner his system has since been superseded by one of a more effective kind, is described under **LIFE MORTARS AND ROCKETS**. Captain M. died November 18, 1854, at Pedestal House, Southtown, near Great Yarmouth. — *Annual Register*.

MANDU', an extensive deserted city of India, in the state of Dhar, in Malwa, 15 miles north of the right bank of the Nerbudda, in lat. 22° 20' N., long. 75° 27' E. The circumference of the ramparts is said to be 37 miles, although it is not probable that the whole of the space was occupied. The greatest and least injured of the ruined buildings is the Jama Masjid, or Great Mosque, the area of which is raised several yards above the ground, and is reached by a large and handsome flight of stairs. It has a very striking appearance. Next in importance is the mausoleum of Hoshung Ghori, king of Malwa, who raised this city to great splendour. It is a massive building of white marble. According to Malcolm, M. was founded 313 A.D. The buildings are principally of Afghan architecture.

MANRE'SA, a town of Spain, in the province of Barcelona, and 30 miles north-west of the city of Barcelona. It is situated in a fertile and well irrigated district, on the left bank of the Cardonet. M. has manufactures of cotton and silk fabrics, broadcloths, &c. In 1811, it suffered severely at the hand of Marshal Macdonald, who set it on fire, when more than 800 houses, with churches and manufactories, were burned down. Pop. 13,339.

MANSEL, **THE REV. HENRY LONGUEVILLE, B.D.**, Waynflete Professor of Moral and Metaphysical Philosophy in Oxford, was born at Cosgrove, Northamptonshire, in 1820, his father being rector of the parish. He was educated at Merchant Taylors' School, and at St John's College, Oxford; and graduated in 1843. In 1855, he was appointed Reader in Moral and Metaphysical Philosophy, in Magdalen College; and in 1859, became Waynflete Professor. In 1867, he received the appointments of Regius Professor of Ecclesiastical History, and Canon of Christ Church, Oxford. His published

works are: Aldrich's *Logic*, with Notes (1849); *Prolegomena Logica* (1851); article *Metaphysics*, in 8th edition of the *Encyclopædia Britannica* (1857), afterwards published separately; *Bampton Lectures—The Limits of Religious Thought* (1858); *The Philosophy of the Conditioned* (1866), in reply to Mill's *Review of Hamilton's Philosophy*. He was co-editor, with Professor Veitch, of Sir William Hamilton's *Lectures*.—Mr M. is considered as belonging to the school of Sir W. Hamilton. He is well versed in the erudition of Metaphysical Philosophy, and writes in a clear and elegant style. His *Bampton Lectures* occasioned much controversy, both theological and philosophical. See **CONDITIONED**.

MANTES (anc. *Medunta*), a town of France, in the dep. of Seine-et-Oise, beautifully situated on the left bank of the Seine, 29 miles west-north-west from Paris, on the railway between Paris and Rouen. M. is a place of great antiquity, and of much historic interest. It was a town of the Celts, from which the Druids were expelled by Julius Cæsar. William the Conqueror took it by assault in 1087, put the inhabitants to the sword, razed the fortifications, and burned three-fourths of the houses; but here he received the injury, through the starting of his horse, which caused his death in a few days. M. has a considerable trade in wheat, large tanneries, and saltpetre manufactories. Pop. (1866) 5186. On the opposite side of the river, connected with M. by bridges and an island, is the village of Limay, with a pop. of nearly 2000.

MARCH, a market-town of Cambridgeshire, England, 29 miles north from Cambridge, on both sides of the Old Nen, which is here navigable for boats, and on the East Anglian Railway. There is a junction of five railways at March. There is a large square market-place in the centre of the town, and a splendid court-house, in which the meetings of the Middle Level Drainage Commissioners are held. Pop. (1861) 3600. In the neighbourhood is *March Wet Fen*, a drained fen with an area of 3600 acres, from which the water is pumped off by steam-engines.

MAR'GAY (*Felis tigrina*), a species of cat or tiger-cat; a native of the forests of Brazil and Guiana; about the same size with the wild cat of Europe; of a pale fawn colour, with black bands on the fore-parts, and leopard-like spots on the hind-parts, and on the rather long thick bushy tail. It has been erroneously represented as untamable, being, in fact, capable of a complete domestication, and of being made very useful in rat-killing.

MARIA'NNA, or **MARIANA**, an episcopal city of Brazil, in the province of Minas-Geraes, about 12 miles east of Ouro Preto. In the neighbourhood are gold, silver, and lead mines. Pop. 8000.

MA'RIENBERG, a town of Saxony, in the circle of Zwickau, 38 miles south-west of Dresden. It has manufactures of linen, lace, and steam-engines, and the neighbouring mines give employment to a great number of the inhabitants. M. has mineral baths, and an establishment for the cold-water cure. Pop. (1864) 5414.

MARINE'O, a town of Sicily, in the province of Palermo, and 11 miles south of the town of Palermo, near a small river which flows into the Gulf of Palermo. Pop. (1861) 8360.

MARI'NO (anc. *Bovilla*), a market-town of Central Italy, in the Comarca, and 12 miles south-east of the city of Rome, near Lake Albano. M. is situated on a high hill above a plain, and is surrounded by strong walls and towers, which were erected by the Colonna in 1480, and add much to

its picturesque beauty. According to the writer of Murray's Handbook, the long street called the Corso, the piazza of the Duomo, and the fountain, would do credit to many towns of more importance. At the foot of the hill of Marino, lying between it and the ridge of Alba Longa, is a deep glen beautifully wooded, called the *Parco di Colonna*. This valley is highly interesting as the site of the *Aqua Ferentina*, memorable as the spot on which the Latin tribes held their general assemblies, from the destruction of Alba to the consulship of P. Decius Mus, 338 a.c. M. is also interesting in the history of the middle ages as the stronghold of the Orsini family, who first appear in the 13th c. in connection with their castle of Marino. In the 15th c., it became the property of the Colonna family, who have retained it almost without interruption to the present time. Pop. 6000.

MARKING-NUT, the fruit of *Semecarpus anacardium*, a tree of the natural order *Anacardiaceæ*, a native of the mountains of India. It is a large tree, with oblong leaves, and terminal panicles of flowers. The fruit is a heart-shaped nut, seated on a large swollen receptacle. The receptacle, when ripe, is roasted and eaten, and resembles a roasted apple; although, when raw, it is astringent and acrid. The nut is black, and between the two coats of its shell there is a black acrid juice, much in use for marking cotton-cloths, a mixture of quick-lime and water being applied, to prevent it from running, and to brighten the colour. It is also used as an external application in rheumatism.

MARSIVAN, or **MARSOVAN**, a village of Asia Minor, in the pashalic of Sivas, and 120 miles north-west of the town of that name, in a wide undulating plain. It is said to contain 6000 houses, of which 1000 are inhabited by Armenians, and it has many mosques and fountains, and some manufactures of cotton stuffs.

MASAY'A, one of the oldest towns of Nicaragua, Central America, close to a lake of the same name, 40 miles north-north-west of Nicaragua city, and eight miles from the north shore of the lake of Nicaragua, near the volcano of Masaya—a broad, low mountain, about 3500 feet high, with one large and several minor craters. The last great eruption of this mountain was in 1670, when the lava spread in a northern direction to a distance of more than 20 miles. This great lava-field is said to resemble an ocean of ink suddenly congealed in a storm. In 1860, the mountain shewed signs of renewed activity. The town is the centre of a very fertile district, and has a pop. of 15,000, chiefly Indians, who are said to be thrifty and industrious.

MASCARA', a very old town of Algeria, in the province of Oran, and 50 miles south-east of the town of that name, on a slope of the Atlas Mountains. M. was built by the Turks upon the site of a Roman colony. During the first years of the French occupation, it was a favourite residence of Abd-el-Kader, but was taken by the French in 1835. Pop. (1861) 8629, of whom 5509 were natives.

MASHE'NA, a town of Bornu, Central Africa, in lat. 13° 3' N., long. 10° 2' E., about 240 miles west of Lake Tchad. It lies on the gentle southern slope of an eminence, the top of which is crowned with a rocky crest, and is surrounded with a clay wall. According to Barth, it is a considerable place for this country, having a pop. of certainly not less than 10,000, but without the least sign of industry.

MA'SSOWAH, or **MASOUA**, an islet and town on the west coast of the Red Sea, in lat. 15° 36' N., and long. 39° 21' E., close to the boundary between

Nubia and Abyssinia. At present, it is politically connected with Nubia rather than with Abyssinia, being in the possession of the Viceroy of Egypt, and ruled by a governor appointed by him. The island is of coral, the soil partly formed from the rock, partly from sand and broken shells. It is only about a mile and a quarter in circumference, and is distant from the mainland only about 200 yards. It is almost wholly occupied by the town, and contains a pop. of about 8000, mostly Arabs. The Abyssinian coast is very destitute of harbours, and M. is of great importance as a seat of commerce. It carries on a large trade by sea with Bombay and with the Arabian coast, particularly with Jiddah and Yembo; and a large trade also by caravans with Cairo on the one hand, and with Gondar and the whole interior of Abyssinia on the other. Caravans start at all seasons for Cairo and for Gondar; but most numerously in January, at the end of the rains, and in June, before the swelling of the waters. Wheat, rice, maize, durra, salt, tobacco, gunpowder, sugar, cotton and silk goods, scarlet cloth, glass wares, arms, and hardwares are among the principal imports from the more distant parts of the world. From Abyssinia and the coasts of the Red Sea, M. receives and exports ivory, rhinoceros' horns, wax, ostrich-feathers, tortoise-shell, myrrh, senna, pearls, &c. M. has all the worst characteristics of an oriental town. Its streets are mere lanes, and excessively dirty. M. was originally chosen as the place of debarkation of the British expedition to Abyssinia (1867), and the starting-point of its operations; but it was soon found unsuitable, and Annesley Bay, about 15 miles further to the south—the deepest inlet on the Abyssinian coast—was chosen for that purpose instead.

MASTER AND SERVANT. There having been reason to complain that the Act 4 Geo. IV. c. 34, under which disputes between masters and servants were generally determined, was a one-sided measure, a parliamentary committee investigated the matter in 1865 and 1866. The result was a bill, introduced by Lord Elcho into the House of Commons, which passed, and forms the Act 30 and 31 Vict. c. 141, called The Master and Servant Act, 1867. This noteworthy statute for the first time places employer and employed on terms of equality—there being no longer room under it for the reproach that a servant could be dealt with criminally for a breach of contract, for which the master was only civilly responsible. Henceforth, both parties have the same remedies. The statute provides that the party aggrieved may lay his information before a justice, or (except in certain districts) a stipendiary magistrate, or (in Scotland) before a sheriff; and thereupon a summons is issued, calling on the alleged offender to appear and answer the charge. Under ordinary circumstances, the case will be heard not less than two, and not more than eight days after the issue of the summons; but it is provided, that if at any time after laying the information, it shall appear that the person complained of is about to abscond, he may be required by a second summons to give security forthwith for his due appearance; and failing his finding such security, may be detained in custody till the hearing. If the complaint is investigated before justices, two at least must be present. After trial, the court may, according to circumstances, either declare the whole or a part of the servant's wages to be forfeited; or else, may order the master or the servant, as the case may be, to fulfil the contract, and (if thought right) to find security for doing so; or else, it may annul the contract, and appoint the wages due under it; or it may fine the offender in a sum not exceeding £20; or fix a

sum due to the offended party for compensation for the injury caused by the conduct of the other party. When a fine is imposed, or damages awarded, the money is to be recovered by execution against the offender's goods; but, in default of payment being had in that way, the offender may be imprisoned (without hard labour) for not more than three months. The possibility of these provisions being insufficient, in the case of the occurrence of any of those aggravated offences which formed the excuse for the more rigorous law which has been superseded, is recognised, and whenever it appears that any injury inflicted on the person or property of the party complaining has been of an aggravated character, and has not arisen in the exercise of a legal right existing, or reasonably and *bonâ fide* supposed to exist, the court may commit the offender to prison, with or without hard labour, for a term not exceeding three months. In all proceedings under the act, the parties themselves are admissible as witnesses. Altogether, the act may be said to remodel entirely the statute law of master and servant.

MASTS, IRON AND STEEL. As far back as 1836, the City of Dublin Steam-packet Company had a steamer with hollow iron masts, the masts acting also as ventilating funnels for the cabins. From that time, iron has been frequently employed for lower masts, in sailing-ships as well as in steamers. The plan has usually been to make them of plates bent to the proper curvature, jointed by internal strips, and strengthened by an internal cross flange of plates secured by angle-irons; but sometimes the plates are lapped. The plates vary from $\frac{3}{4}$ to $\frac{1}{2}$ inch in thickness. Mr Grantham (*Iron-shipbuilding*) states that iron masts are 'lighter and stronger than timber masts; and when compared with the built-up masts of large vessels, are rather less expensive. For vessels of the same tonnage, the difference of weight is nearly two to three in favour of iron.'

Iron is used for yards as well as masts. An iron yard was made in 1847 for the Australian clipper-ship *Schomburgk*, 112 feet long, and varying in diameter from 14 to 28 inches; it weighed $7\frac{1}{2}$ tons. It was calculated that a timber yard of the same size would weigh $12\frac{1}{2}$ tons. Iron masts have since that time been employed in many ships in the royal navy, made of three vertical ranges of plates bent to the required curvature, with butt joints, and riveted to three T-irons which cover the joints on the inside.

Captain Cowper Coles, the inventor of the turret system for ships of war, has introduced tripod iron masts of peculiar construction. The real mast is strengthened and upheld by two others, the three forming a tripod. The central tube, or real mast, is carried up to form the topmast; while the side tubes are carried up only to the height of the lower yard. The main tube rests upon the keelson; while the side tubes, which are on either side of it and behind it, rest upon parts of the bottom-framing; but all three are fastened to the deck as they pass through. The lower mast only forms the tripod, and is self-supporting, without shrouds, &c.; the topmast is secured with stays, backstays, and outriggers. Captain Coles enumerates many advantages which he believes this construction to possess.

Since the use of steel in shipbuilding has become recognised, the employment of the same metal for masts has engaged attention; steel plates, we know, can now be made almost as easily as plates of iron; and it becomes a question of increased efficiency against increased cost as to which metal shall be adopted. In some experiments made at the beginning of 1867, at an engineering establishment in Southwark, it was found that Bessemer

steel has more tensile strength than Millwall iron for masts; and that Deane's steel is better than Bessemer's. Steel being more tough than iron, weight for weight, a ship's set of masts would be less ponderous in the former metal than the latter.

Masts of Iron.

Actual use in war and in stormy weather would be necessary, however, to determine all the relative advantages of iron and steel for masts.

The subject of the stability of iron masts is treated with much fulness by Mr Lamport, in a Paper read before the Institute of Naval Architects in 1863.

MATIN DOG, a large kind of dog, now almost peculiarly French; but supposed to have been introduced into France from the north of Europe. It is allied to the Danish dog. It has rough hair; a rather flat forehead; a rather pointed muzzle; the ears erect, but bent down at the tips. It is generally of a whitish colour, clouded with brown. It is fierce, but not very courageous. Buffon, without reason, imagined it to be the original of many kinds of dog.

MA'TSUMAI, a town and port of Japan, and the largest centre of commerce and population in the island of Yesso. It is on the south coast, about 60 miles west of Hakodadi, and contains, it is said, 60,000 inhabitants. It extends along the margin of an open bay, facing which is an island with a beacon, sheltering a harbour capable of receiving the largest ships.

MAURICE (DUKE and afterwards ELECTOR) OF SAXONY, eldest son of Duke Henry of the Albertine line (see SAXONY), and nephew of Duke George (q. v.) the Bearded, the most bitter opponent of the Reformation, was born at Freiberg, 21st March 1521; espoused, in 1541, Agnes, daughter of the Landgraf Philip of Hesse; and later in the same year, succeeded his father in the duchy of Saxony and its dependencies. He was hardly well established in his dominions, till a dispute arose between him and his cousin, the Elector John Frederic, regarding their respective rights over the bishopric of Meissen, which was the common property of the Ernestine and Albertine lines; but by the influence of Luther

and of the Landgraf Philip, a temporary reconciliation was effected. M. took part in the campaign of 1542 against the Turks in Hungary, and gave such signal proof of military talent, that the Emperor on his return eagerly pressed him to accept a command in the armies on the western frontier of Germany. M. was nothing loath to continue his military career, but insisted on obtaining the protectorate of the bishoprics of Magdeburg and Halberstadt, in recompense of his services; a stipulation to which Charles would not consent. M. accordingly returned to his duchy, and though still on the most friendly terms with the Emperor, took part in the deliberations of the Protestant League of Schmalkald (q. v.), being himself a professed Protestant, and the son-in-law of one of the chiefs of the League. He refused, however, though agreeing with the objects of the League, to become a member; and the judicious gift to him by the Emperor of the much-coveted protectorate above mentioned, and subsequently (19th June 1546), a solemn deed of the Emperor at Ratisbon, by which the Ernestine portion of Saxony and the electoral title were transferred from John Frederic to M., secured the latter's energetic support. When Charles, at the commencement of the war, was cooped up in Southern Germany by the army of the League, M., by invading the Saxon electorate, compelled the Protestants to retire northwards, thus relieving the emperor, and enabling him to subdue Swabia and the Upper Rhine districts. But by this manœuvre he drew an overwhelming attack upon himself, and was driven by the incensed John Frederic from the electorate, deprived of his own dominions, and reduced to extremity. At this critical moment, the Emperor came to his aid; and M. and the Duke of Alva (see ALVA), at the battle of Muhlberg, annihilated the elector's army, and took himself prisoner. M. was now, in accordance with the previous agreement, ruler of the whole of Saxony, with the electoral dignity; and having obtained from the Emperor all the gratification of his ambitious desires which could be hoped for from that quarter, their friendly relations became more dependent upon the course of events. The retention in confinement of Philip of Hesse, whom M. had prevailed upon to submit to the Emperor, was the first cause of estrangement; the incessant attempts of the Emperor to increase, by modifications of the imperial system, his own preponderance in Germany, supplied another; and though the new elector zealously supported the Interim (q. v.) of Augsburg in 1547, he gradually came to see that his close alliance with the Emperor was alienating from him the affections of his Protestant subjects. He accordingly at once abandoned the cause of the Emperor with as little scruple as he had formerly sacrificed the interests of his relatives and co-religionists; and, in common with the princes of Kulmbach and Hesse, secretly sent (May 1551) agents to Paris and London to negotiate an alliance against Charles V., while he leisurely carried on the siege of the rebellious city of Magdeburg, in order to have a pretext for keeping an army afoot. Meanwhile, Charles, at Innsbruck, was employing himself in building up vast schemes of ambition, little dreaming of the mine which the man whom he most of all confided in was preparing to spring under his feet; till the manifesto, or rather ultimatum of the Protestant princes, in which they demanded the release of Philip of Hesse, and the total abolition of the arbitrary authority of the imperial government; and the capture by them of Augsburg, while their allies, the French, took Metz; rudely drew away the veil from his eyes. Without money, without troops, without allies, nothing but a secret flight from Innsbruck appeared open to him; but he had only got as

far as Füssen (a town on the Lech, on the borders of Bavaria and the Tyrol), when the news that M. was marching in this direction, forced him to hasten again to Innsbruck. On April 18, by the mediation of Ferdinand, king of the Romans, a treaty was concluded at Linz granting the demands of the Protestants; but as it was not to take effect till May 26, M. employed himself in attacking (May 18) the camp of Reitti, in which soldiers were being assembled for the Emperor, defeated and wholly dispersed the imperialists, and advanced on Innsbruck with the view of taking Charles captive, when his progress was stopped by a mutiny in his army; and the Emperor escaped. His advance on Innsbruck so alarmed the members of the Council of Trent, that they fled from the town, and the sittings were thenceforth suspended for some years. Finally, at a convocation of the electors and princes of the empire at Passau, the terms of a treaty of peace were discussed, M. directing the cause of the Protestants, and Ferdinand attending to the imperial interests; and it was ultimately agreed that Protestants were free to exercise their mode of worship; that the imperial chamber, from which Lutherans were not to be excluded, should render justice irrespective of religion; and that the Aulic Council should be composed exclusively of German ministers. These conditions, which in political matters secured 'Germany for the Germans,' and in religious affairs permanently established the principles of toleration, were embodied in the agreement called the *Peace of Passau* (22d August 1552). The bitter dislike conceived by the Emperor towards M. on account of these transactions, prompted him to entertain the idea of deposing him from the electorate, and reponing John Frederic; of which scheme, M. being apprised, he, with his usual subtlety and address, patched up a reconciliation with the Emperor, and went to take part in the campaign of 1553 against the Turks, who were gradually gaining ground in Hungary. Returning soon, he found that one of his former allies, Albert, Markgraf of Kulmbach, had refused to accede to the treaty of Passau, and continued the war on his own account, making raids on the ecclesiastical princes of the Rhine and Franconia. M. speedily discovered that the markgraf's apparent obstinacy was the fruit of a secret understanding with the Emperor, who was anxious to secure the services of a general and army capable of wreaking his vengeance on the perfidious Saxon prince. So, about midsummer of 1553, M., putting himself at the head of 20,000 men, marched to protect his bishopric of Magdeburg against the ecclesiastical spoliator, and falling in with him at Sieverhausen, completely defeated him (9th July), but received in the conflict a bullet-wound which proved fatal, July 11, 1553. Thus fell, at the early age of 32, a prince who had already established his reputation as one of the ablest generals and diplomatists of his time. So thoughtful and reticent, so enterprising and energetic, so correct in judgment and unfailing in action, and at the same time so wholly devoid of moral sentiment, he is one of the most prominent instances of power without principle which the world's history has ever presented. His calculating, plotting mind was concealed under a jovial exterior, and a genuine fondness for the favourite pastimes of the age. Yet this unprincipled dissimulator's states were the best governed of the empire; the great vassal was equal with the meanest peasant in the courts of justice; great advances were made in education; and though the least religious man of the time (in fact, honest only in this point, that he did not pretend to a piety which he did not feel), the rights of the various religious sects were strictly maintained. He died at an epoch

which was big with the fate of Germany; for his settled programme of action was, after defeating the markgraf, to march upon the Low Countries, unite with the French, with whom he had formed a firm alliance against the Emperor, and then attack the latter. Charles V. would have had apparently little chance of offering a successful resistance to such an overwhelming attack.—See the biographies of this remarkable man by Reutter, Camerarius, Arnold, Schleukert, and Langenn.

His surviving daughter, Anne, became the wife of William of Orange, the liberator of the Netherlands.

MAXIMILIAN, EMPEROR OF MEXICO, otherwise FERDINAND MAXIMILIAN JOSEPH, Archduke of Austria, was born on July 6, 1832. He was the son of the Archduke Francis Charles, and the younger brother of Francis Joseph I, who became Emperor of Austria in 1848, by virtue of acts of abdication and renunciation by his uncle and father. M., who received a careful education, and shewed himself an apt pupil, entered the Austrian navy, and while in that service, visited Italy, Spain, Algeria, Albania, and Madeira, all of which are admirably described by him in a work mentioned below. He married on July 27, 1857, Charlotte Marie Amélie, born June 7, 1840, a daughter of Leopold I, king of the Belgians. After holding for a time the rank of vice-admiral, he abandoned the navy, and became governor of the Lombard Venetian Kingdom. In this post, he became a popular idol—thanks to his fine person, affable and graceful manners, and the conscientious manner in which he discharged his arduous duties. In 1861, he was named President of the Upper House; but he resigned the office in the same year, and shortly afterwards visited England. At this period, events were taking place in America destined to bring him into more prominent notice. In 1860, the office of President of Mexico had devolved upon Benito Juarez, as chief judge in the supreme court. He had just triumphed over the clerical party, after a struggle of three years' duration. The confiscation of church property, and the suspension of the payment of European debts—measures now admitted to have been unavoidable—served as a pretext for an appeal on behalf of the Mexican clergy for European assistance. The French were induced to interfere, perhaps in the belief that the whole population was opposed to the liberal government. The French general, with the heads of the Mexican church and army, when the city of Mexico had been taken, called together what they described as an Assembly of Notables; and this body, in July 1863, decided that a monarchy, not a republic, was the form of government best suited to the interests and character of the people of Mexico. M. was pointed out as the European prince who by his birth and character would most worthily wear the crown, and a deputation was appointed to offer it to him. Few expected that he would entertain the proposal, but he did so on consideration of duty. He insisted, however, on having evidence that the population were in his favour. This was easily obtained, the political and municipal offices having been filled by Conservatives appointed by the French; and the scruples of M. were overcome. On April 9, 1864, he signed a family pact, by which he renounced, under certain conditions, his rights as an Austrian prince; and on the following day, he solemnly accepted the crown of Mexico. On the 14th, he set sail for his dominions. On June 12, he entered Mexico. He was of course warmly welcomed by the clergy and the army; but he soon found that they and he could not agree. They expected him to sanction abuses which he felt bound,

as an honest man and enlightened prince, to condemn openly as gross scandals. The Liberals, on the other hand, found him an ardent supporter of all the principles they had for a generation been contending for, and he gained their support. He formed a Liberal cabinet, including even some of those who had been ministers under Juarez. His laborious habits, practical acquaintance with administration, and exemplary life, secured the esteem and support of many persons who had stood aloof from party disputes; and his position was still further improved by the influence of the empress with the educated classes of the capital. For a time, all went well, and M. devoted his whole energy to inquiries into grievances, the promotion of banking and railway projects, and a scientific commission in which he took a deep and special interest. The great mistake he made was to hear and attempt to reconcile Mexican parties, who had no other object in view than power and place. He could not restore to the clergy their confiscated estates, but he sought to appease them, and was pronounced a traitor. Then all reform of the finances was prevented by the French demands for compensation, and this difficulty brought him into collision with the Liberals. Their opposition was unfortunately confirmed by a proclamation he was induced to make on October 2, 1865, threatening to punish with death under the laws of war all who offered resistance to the government, the republic having ceased not only by the will of the nation, but by the expiration of the administration of Juarez, and his flight to the United States. This decree he was told was asked for merely to suppress brigandage, but it was employed both by the Imperialist and French commanders as a sanguinary edict, under which many estimable Liberal officers were cruelly shot as robbers. The northern states of Mexico had always retained a sort of independence before the foreign occupation of the southern provinces, and the French had not reduced them to subjection. There Juarez and his followers again raised the standard of independence, and harassed the French army. At the same time, the success of the North in the American war, and the dissatisfaction of the French people with the cost of the Mexican expedition, compelled Louis Napoleon to contemplate the withdrawal of his troops. In vain the empress went to Europe to enlist support for her husband, who had lost all his private fortune. She found that he had proved too honest for some of his old friends, and her reason gave way under the continued grief and excitement brought on by disappointment. The Belgians and Austrians would have replaced the French legions, but the threats of America compelled them to abandon the enterprise. The French, too, were compelled to retire, and they were undoubtedly most anxious that M. should leave with their troops; but he felt bound as a man of honour to remain, and share the fate of his followers. In doing so, he placed himself at the head of a Mexican faction without the excuse of subjection to the French. At the head of 10,000 men, he made a brave defence of Queretaro against a Liberal army under Escobedo. On the night of May 14, 1867, General Lopez betrayed him. This man whom he believed to be his dearest friend, gave up to Escobedo one night the strongest position in the imperial encampment—that where the emperor slept. The Mexican officer who took possession tried to induce M. to escape as a civilian; but he declined to do so, at the risk of compromising even an enemy. The Liberal Minister of War ordered M. and Generals Miramon and Mejia to be tried by court-martial; and it was in vain the European ministers protested against this breach of the

laws of civilised warfare. How far Juarez interfered on behalf of M. is not well ascertained, but certain it is that he at length acquiesced in the decision of his cabinet. The court-martial consisted of a president, aged 23, and six other members, between the ages of 18 and 20. The trial was of course a mere farce, and the charges chiefly rested on the proclamation above referred to and the executions which followed it. At seven in the morning of July 19, the three prisoners were removed in carriages to the place of execution. Four soldiers were detailed for each prisoner, and it was arranged that all should be shot at the same time. M. said to those present that he forgave all, as he hoped to be forgiven, and that he trusted his blood would be for the good of Mexico. He then placed his hand on his breast, to shew the soldiers where to fire, and opened his arms. The soldiers fired at once. Miramon died immediately. The emperor was wounded by the four balls; but he did not die till three unavailing attempts had been made to terminate his sufferings. The poor Indians who were present at the execution wept aloud, and rushing forward, wiped up every drop of blood which fell. The account given of the execution by the emperor's servant Tudos, and confirmed by other eye-witnesses, filled Europe with indignation, and exposed the Mexican Liberals to abuse not altogether merited. Since the death of M., his writings have been collected, and several volumes are already published under the title of *Aus Meinem Leben: Reisekizzen; Aphorismen Gedichte*. This work is remarkable for its elegance of style, and it gives ample evidence of the ability and varied attainments of the author, of his good sense, enlightenment, candour, generosity, and scorn for every kind of meanness. After some delay, the body of M. was given up to his relatives, and was conveyed to Europe in an Austrian frigate.

MAYMEMÉ, a city of Bokhara, capital of a khanat of the same name, about 200 miles north of Herat, on a river flowing north towards the Jihun, but only part of which has as yet been traced. It consists of about 1500 mud huts, a frail bazaar built of brick, three mosques of mud, and two *medresse*, or colleges, of brick. It is considered by the natives to be a powerful stronghold, but its only defences are a simple wall of earth around the city, 12 feet high, and 5 feet broad; and a citadel surrounded by a fosse, and situated upon a conspicuous hill of steep ascent. The people of the town, as well as those of the khanat, are bold and fearless riders, and of resolute, warlike character. According to Vámbéry, he who would wish to take Bokhara must destroy M., or be sure of its friendly feeling.—Vámbéry's *Travels in Central Asia*.

MAYOTTA, one of the Comoro Isles (q. v.), ceded to France in 1843, lies in lat. 12° 34'—13° 4' S., and long. 44° 59' 15"—45° 23' E. It is of irregular form, and measures 21 miles from north to south, with an average breadth of six or seven miles: if, however, the dangerous coral reefs which surround the island be included, the whole occupies a space of 30 miles north and south, and 24 miles east and west. The surface of M. is very uneven, and is studded with volcanic-looking peaks, some of which exceed 2000 feet in height. The shores of the island are in some places lined with mangrove swamps, which are uncovered at low water, and are productive of malaria and fever. The island is in most parts capable of cultivation, and contains eleven sugar-plantations, said to yield a total of 3000 tons, although there is reason to believe that this estimate is exaggerated. Nothing but sugar is exported; and the supply of food grown on the

island is insufficient for the use of the inhabitants. The total yearly produce of the island may be estimated at £40,000. As a colony, M. has certainly not fulfilled the expectations entertained by the French at the time of its occupation, notwithstanding the unusually liberal terms held out to the colonists. The French establishment is on the island of Zaondzi, inside the chain of reefs on the east side of M., and consists of a governor, colonial officer, some artificers and seamen, and about 100 soldiers, besides a few native ones. There are several substantial government buildings and store-houses, and numerous huts. There is a good roadstead, and the fort has been recently fortified. M. is the only refuge for French ships in the Indian Ocean. It is the principal market for the neighbouring islands. Pop. (1864) about 8000.

MAZAMET, a town of France, dep. of Tarn, 43 miles east-south-east of Toulouse, on the Arnette, a feeder of the Tarn. It has extensive woollen manufactures and cloth-fairs. Pop. (1866) 9757.

MAZARRON, or **ALMAZARRON**, a seaport town of Spain, in the province of Murcia, 27 miles west-south-west of Cartagena, on the coast of the Mediterranean. The inhabitants are employed in fishing and mining—silver ores and alum being found in the neighbouring hills. Much barilla is made here. From the number of ruins found in the vicinity, this is supposed to have been the site of an important Carthaginian settlement. Pop. about 7000.

MAZUFURABA'D, a town of India, in the Punjab, about 200 miles north-north-west of Lahore, at the confluence of the Jhelum and its great tributary, the Kishengunga, over both which rivers there are ferries. It is of importance chiefly on account of its commanding position at the entrance of the Baramula Pass into Cashmere. The Emperor Aurungzebe built a fort here, which was subsequently replaced by one of greater strength, erected by the Afghan governor, Ata Mahomed.

MEDE'AH, a town of Algeria, 43 miles south-south-west of the town of Algiers, consists of a walled town and suburbs. It is considered as, on the whole, one of the finest towns in Algeria. There is an Arab market held every Friday. Under the Romans, M. was a military station. Pop. (1861) within the walls, 2100; without the walls, 5700: total, 7800.

MEDINA DE RIO SECO (anc. *Forum Egororum*), a town of Spain, in the province of Valladolid, 22 miles north-west of the city of Valladolid, on the Sequillo, an affluent of the Douro. This place was a famous emporium in the 14th c., when its cloth and linen fairs were amongst the greatest in the kingdom; it is now a place of little or no importance whatever. There still exist some remains of its former greatness, in its arcades, arches, ruins of a palace, &c. In 1808, the town was given up to pillage by Bessières. Pop. 5100.

MEE'RAÑÉ, a prosperous manufacturing town of Saxony, in the circle of Zwickau, ten miles north of the town of Zwickau. Until within the last few years, it was an unimportant, small country town; but it has recently increased rapidly in size and importance, through the development of its industrial resources. Its pop., in 1849, was 7345; 1858, 11,147; 1861, 13,626; 1864, 15,714. The manufactures produce, almost exclusively, woollen and mixed fabrics; and in 1863, employed 15,000 looms, of which about 3000 were in the town itself, and the rest elsewhere. In 1866, there were upwards of 100 manufactories, the yearly products of which were estimated at upwards of £2,000,000. A large export trade is carried on with England, France,

and America, three of the principal firms having set up establishments in New York. There are some large tanneries in Meerane. The town itself has within the last few years been very much improved.

MEIAPONTÉ, a town of Brazil, in the province of Goyaz, about 80 miles east-north-east of the town of Goyaz, on the river Almas. In the neighbourhood are some gold mines; and the district produces millet, barley, cotton, tobacco, and sugar. Pop. 8000.

MEKLO'NG, a town of Siam, at the confluence of the Meklong river with the west mouth of the Menam, 30 miles south-west of Bangkok. Pop. estimated at 10,000. The province furnishes salt for all the kingdom.

MELA-BOSA, a fruit of the genus *Citrus*, and probably a variety of the Lime (q. v.), cultivated in Italy. It receives its name from its fragrance being thought to resemble that of the rose. It is a small flattened fruit, with a protuberance at the tip, from which many raised ribs proceed in a star-like form to the circumference. The skin is yellow, thin, and adheres closely to the pulp.

ME'LFÍ, an ancient episcopal town of Southern Italy, in the province of Basilicata, 32 miles south of Foggia, on a feeder of the Ofanto (anc. *Apudus*). It is situated on a bed of lava to the north-east of the lofty (3000 feet) volcanic Monte Volture, now extinct, from which it is separated by a deep ravine. The once magnificent cathedral, erected in 1155, was almost entirely destroyed by an earthquake in 1851, which at the same time levelled many fine buildings, public and private, and destroyed about 1000 persons. The only evidences of volcanic action are the severity of the earthquakes which occasionally desolate the district, and the emission at times of carbonic acid and other gases from the lakes in the old crater of the volcano, throwing up columns of water, accompanied by internal rumblings. This phenomenon generally takes place when Vesuvius is in a state of activity. The district around the city is celebrated for its wine. Pop. (1861) 9803.

MELI'O'CCA, a genus of trees or shrubs of the natural order *Sapindaceæ*, one of which, *M. bijuga*, a native of the West Indies, is there universally cultivated for its fruit. It is called the **HONEY BERRY**, and the *Jamaica Bullace Plum*; by the Spaniards, *Monos*, and by the Dutch, *Knipsee*. It is from 16 to 20 feet high. The fruit is jet black, about the size of a bullace. The seeds are roasted, and eaten like chestnuts. Other species of *M.* yield eatable fruits.

MEN'FI, or **MENFRICI**, a town of Sicily, in the province of Girgenti, 43 miles south-south-west of Palermo, crowns a long bare height, about three miles from the coast. Pop. (1861) 9938.

MENHADEN (*Alosa menhaden*), a fish of the same genus with the Shad (q. v.), which is caught in great quantities on the coasts of New York and New England during the summer months, when it visits them for the purpose of spawning. Its length is from 8 to 14 inches; the colour of the upper parts is greenish brown, the belly silvery, a black spot on the shoulder, the whole surface iridescent. The *M.* is not a very palatable fish, but is rich in oil, which is used by painters, and is considered superior to linseed oil. Great quantities of this fish are taken in some seasons, and are sold for manure, one fish being considered equal to a shovelful of barn-yard manure, and 2500 sufficient for an acre of land.

MERCHANT SHIPPING ACT of 1854 (stat. 17 and 18 Vict. c. 104), a measure which in many important respects amended, and at the

MERCHANT SHIPPING ACT.

same time consolidated, the law of this country relative to merchant shipping. It was framed and carried through parliament by Lord Aberdeen's government, under the special charge of Mr Lowe, Vice-president of the Board of Trade. By the Merchant Shipping Repeal Act of the same year (stat. 17 and 18 Vict. c. 120), the statutes relative to merchant shipping previously in force were, with one or two unimportant exceptions, repealed; the new act, which formed an almost complete code of the laws affecting merchant-ships, coming in their place. Three acts have since been passed, in some respects amending, but to a greater extent supplementing, the act of 1854—the Merchant Shipping Act Amendment Acts, 1855 and 1862 (stat. 18 and 19 Vict. c. 91, and stat. 25 and 26 Vict. c. 93), and the Merchant Shipping Act, 1867 (stat. 30 and 31 Vict. c. 124). The act of 1854 is divided into 11 parts; and the provisions of the two amendment acts are in general referred to the part of the principal act to which they severally belong, so as to facilitate the reading of the three acts conjointly. The act of 1867, with the exception of two unimportant clauses, is occupied with a single subject—the enforcement of proper sanitary conditions on board ships.

The general superintendence of matters relating to merchant-ships and seamen is, by the act of 1854, Part I, intrusted to the Board of Trade. This department is empowered to issue forms of the various books, instruments, and papers required by the Shipping Acts, and to alter the forms when necessary. Returns are, on its requisition, to be made to it by local bodies and officials; and it is invested with powers for compelling local bodies, and shipowners or shipmasters, to perform the duties which the Shipping Acts impose upon them.

British ships, their ownership, measurement, and registry, is the subject of Part II. of the act of 1854. And it is provided that no ship shall be deemed a British ship unless she belong wholly to owners who are of one of the following descriptions: 1. Natural-born subjects; 2. Persons made denizens, or persons naturalised in terms of an act of parliament, or an act of the legislative authority of some British possession; 3. Bodies corporate established under, subject to the laws of, and having their principal place of business in the United Kingdom, or some British possession. But no natural-born subject who has taken the oath of allegiance to any foreign state can be owner of a British ship, unless he has subsequently taken the oath of allegiance to her Majesty; and he must also—so likewise must every denizen or naturalised person—continue, during his ownership, resident within her Majesty's dominions, or else be a member of a British factory, or partner in a house actually carrying on business within her Majesty's dominions. Every British ship, with a few unimportant exceptions, must be registered; and a ship, unless registered, though subject to all the ordinary liabilities, is not to be recognised as a British ship. The registration is to be made by the principal officer of Customs for the time being at any port or place in the United Kingdom approved by the Commissioners of Customs for the registry of ships; and by certain specified officers in the colonies and possessions abroad. The registration is to comprise the name of the ship, which cannot afterwards be changed, and the names and descriptions of the owners; also the tonnage, as ascertained by specified rules, the build, and description of the vessel, the particulars of her origin, and the name of the master. A certificate of registry, containing all the particulars registered, is given by the registrar to the master. On this certificate, changes in the ownership and changes of the master

are endorsed as they occur; and a new certificate may be granted, after certain formalities, in exchange for a former one, or in the event of a former certificate being lost. The master is the person entitled to the custody of this document, and it is a penal offence to detain it from him, upon whatever pretence of right or title. The certificate is given up to the registrar on the ship being lost, or ceasing to be British.

The property in every ship is, for purposes of registration, divided into sixty-four shares. No person is entitled to be registered as owner of any fractional part of a share; but any number of persons not exceeding five may be registered as joint-owners of a share. Counting joint-owners, who are not entitled to dispose in severality of their respective interests, as constituting one person only, not more than thirty-two persons can be registered at the same time as owners of a ship. The power of disposing of the ship or its shares is vested exclusively in registered owners. Notwithstanding this, persons beneficially or equitably interested are to have their interests protected upon application to the proper court. When a registered ship, or any share therein, is disposed of to persons qualified to be owners of British ships, the transfer must be made by a bill of sale under seal, according to a form prescribed, and the names of the transferees are to be entered on the register as owners of the ship or share. Mortgages also must be in a form prescribed, and are to be recorded by the registrar upon production to him in each case of the mortgage deed.

In Part III., under the heading 'Masters and Seamen,' it is provided that local marine boards shall be established at certain ports of the United Kingdom; and that each of these shall consist of two *ex officio* members—the mayor or provost, and the stipendiary magistrate of the place—four members appointed by the Board of Trade, and six elected annually by the owners of foreign-going ships and of home-trade passenger-ships. The local marine board is required to establish an office (called the Shipping Office in the act of 1854, but now, under the act of 1862, called the Mercantile Marine Office) or offices, under the management of a superintendent (originally called shipping-master), whose duty it is to afford facilities for engaging seamen, by keeping registries of their names and character; to superintend and facilitate their engagement and discharge; to provide means for securing the presence on board at the proper time of men who are so engaged; to facilitate the making of apprenticeships to the sea-service; and to perform such other duties relating to merchant-seamen and merchant-ships as shall be committed to them by the Board of Trade. The local marine boards are also required to hold examinations for persons who intend to become masters or mates of foreign-going ships or home-trade passenger-ships. And no person can be employed in a foreign-going ship as master, or first, or second, or only mate, or in a home-trade passenger-ship as master, or first or only mate, unless he holds a certificate of competency obtained at such an examination; or else a certificate of service obtained in virtue of his having held a certain rank in the royal navy, or certain employment in the merchant service previous to the passing of the act of 1854, as specified in the act. The act of 1862 extended the requirement of a certificate from the Board of Trade to engineers employed in steamships. There are first and second class engineers' certificates, and an engineer cannot be employed unless he holds the one or the other—according to his employment and the engine-power of the ship—obtained at an examination, or else in consideration

of his service previous to 1862, or of the rank he has held in the royal navy.

The master of every ship, excepting ships of less than eighty tons burden, exclusively employed in the coasting-trade, is required to enter into an agreement—in a form prescribed by the Board of Trade—with every seaman whom he takes to sea from any part of the United Kingdom. This document, which must be signed by the master and by the seamen, sets forth the nature and duration of the voyage; the number and description of the crew; the time at which each seaman is to be on board, or to begin work; the capacity in which he is to serve; the amount of his wages; a scale of provisions; regulations as to conduct; and such punishments for misconduct as the Board of Trade shall have sanctioned, and as the parties shall have agreed to adopt. In the case of foreign-going ships, the agreement must be made before, and be attested by the superintendent of the Mercantile Marine Office; and seamen engaged abroad must be engaged, if at a colonial port, in the presence of a shipping-master or Customs officer; if at a foreign port, in the presence of the consul. The discharge of the crews of foreign-going ships must be made at the Mercantile Marine Office before the superintendent, to whom the ship-master must deliver a full account of the wages due to each seaman, and of all deductions made from them. It is enacted that no right to wages shall be dependent on the earning of freight; and that every stipulation on the part of the seaman for abandoning his right to wages in the event of the loss of the ship, shall be inoperative. Seamen are enabled to sue in a summary manner for their wages (if not exceeding £50) before two justices, or, in Scotland, before the sheriff; and if discharged abroad, in consequence of the sale or wreck of the ship, or of other similar causes, they must be discharged before some functionary, receiving from the master a certificate of discharge, and be sent home at the expense of the owner. Some provision was made in the act of 1854 as to the amount of space to be set apart for the accommodation of every seaman, as to the maintenance of the sleeping-places in a proper state of order and ventilation, and as to the supply of medicines for the voyage; but the clauses of that act relating to these subjects have been repealed, and fuller provision for them has been made by the act of 1867. In this act, special precautions have been taken to insure that ships take to sea with them a sufficient supply of lime-juice and other anti-scorbutics; and the local marine boards are empowered to appoint medical inspectors to examine seamen applying for employment, if the ship-master desires it.

The act of 1854 provided for the establishment in the port of London of a general register and record office for seamen, under the management of a registrar-general of seamen; and required returns to be made to this official by the officers of Customs, and through superintendents of mercantile marine offices, by masters of ships both in the home and in the foreign trade, from which a general view might be had as to the state of our mercantile marine. Official log-books, in forms prescribed, are required to be kept in every ship, other than those exclusively employed in the coasting-trade, either in connection with or distinct from the ordinary log-book; and in these, entries must be made of numerous specified occurrences. Provision is made for the punishment of offences against discipline and good-conduct committed either by seamen or by ship-masters, and for the trial in this country of persons charged with any crime committed upon the high seas. The Board of Trade may suspend or cancel the certificate (whether of competency or

of service) of any master or mate (1) if, after investigation, he is reported to be incompetent, or to have been guilty of any gross act of misconduct, drunkenness, or tyranny; (2) if, after investigation, it is reported that the loss or abandonment of, or serious damage to any ship, or loss of life, has been caused by his wrongful act or default; (3) if he is superseded by the order of any Admiralty court, or naval court held abroad under the provisions of the act; or (4) if he is shewn to have been convicted of any offence.

In Part IV., under the head of 'Safety and Prevention of Accidents,' rules are laid down as to the boats and life-buoys which are to be carried by sea-going ships; and it is provided that the officers of Customs shall not grant a clearance to any vessel by which those rules have not been complied with. As to the use of lights and fog-signals on board ships at sea, the regulations now in force are contained in the schedules of the act of 1862; where is also laid down the rule of the road for preventing collisions between ships meeting each other at sea. Certain stringent provisions are made as to the build and equipment, and also as to the surveying and certificating of steam-ships.

For the provisions as to pilotage, contained in Part V., we must refer to the acts themselves. See also *Pilot*.

Part VI. deals with the subject of light-houses. See *LIGHT-HOUSE*; *TRINITY HOUSE*; and *NORTHERN LIGHT-HOUSES IN SUPPLEMENT*.

Part VII. relates to the Mercantile Marine Fund. To this fund are to be carried all fees and other sums (other than fines and forfeitures) received by the Board of Trade under the provisions of the 3d and 4th parts of the act; all light-dues or other sums received by the general light-house authorities, under the 6th part; the lastage and ballastage dues received by the Trinity House; and the fees received by the receivers of wreck, under the 8th part of the act. Out of it are to be paid the expenses of the local marine boards; the expenses incurred by the general light-house authorities; any sums appropriated by the Board of Trade for maintaining life-boats, &c.

Part VIII. makes provision for cases of wreck, casualties, and salvage. An inquiry is to be made whenever any ship is lost, abandoned, or materially damaged on or near the coasts of the United Kingdom; or causes loss or material damage to any other ship on or near such coasts; whenever, by reason of any casualty on board of any ship, on or near such coasts, loss of life ensues; and whenever any such loss, abandonment, damage, or casualty happens elsewhere, and any competent witnesses thereof arrive at any place in the United Kingdom. This inquiry is to be made by the inspecting officer of the Coastguard, or the principal officer of Customs of the place at which the occurrence in question happened, or of the place at which competent witnesses of it arrive, if it has happened abroad, or can be conveniently examined; or by some other person appointed for the purpose by the Board of Trade. Such officer or person, if he thinks fit, or if the Board of Trade so directs, may have the matter formally investigated before two justices or a stipendiary magistrate; and the Board of Trade may appoint some person of nautical skill and knowledge to act as assessor to such justices or magistrate. If the conduct of any master or mate is in question, the magistrates may require him to deliver up his certificate pending the inquiry; and the certificate may be cancelled or suspended by the Board of Trade upon their report. The Board of Trade has the general superintendence of all matters relating to wreck, and has power to

appoint a receiver of wreck in any district. Salvage out of property saved is payable whenever within the United Kingdom any ship or boat is in distress, and services are rendered in assisting such ship or boat; in saving the lives of the crew, or in saving the cargo or apparel of such ship or boat; and whenever any wreck is saved by any person other than a receiver; so also all the expenses properly incurred in rendering such services or saving such wreck. Salvage in respect of the preservation of life, has priority over all other claims for salvage; and when the vessel aided has been lost, or the value of what is saved is insufficient to pay salvage after paying the actual expenses incurred, sums may be paid in respect of it by the Board of Trade out of the Mercantile Marine Fund. Disputes with respect to the amount of salvage are to be referred to the decision of any two justices resident at or near the place where the services were rendered, or at or near the place into which the ship or boat has been brought after the services were rendered, when the amount claimed does not exceed £1000; greater amounts may, by consent, be similarly referred; or they may be sued for in the Admiralty courts in England and Ireland, and in the Court of Session in Scotland. The justices may, if they think fit, call in a person conversant with nautical affairs to advise them as assessor, or as an umpire to decide any difference that may arise between them; and the justices, and also the umpire, are in general required to give a decision within 48 hours of the matter having been referred to them. Where the sum in dispute exceeds £50, an appeal may be taken from the decision of the justices to the supreme courts already mentioned. When there is any dispute between the parties entitled as to the apportionment of salvage, the sum due is to be paid to the receiver of wreck, who is empowered to make an apportionment. The Amendment Act of 1862 enables the Lord-lieutenant of Ireland to appoint in any borough or county a rota of justices, by whom jurisdiction in salvage cases shall be exercised, and makes it competent for any stipendiary magistrate, in England for any county court judge, in Scotland for the sheriff or sheriff-substitute, in Ireland for the recorder of any borough, or for the chairman of the quarter-sessions in any county, to exercise the same jurisdiction in salvage cases as is given to two justices.

Part IX. relates to the liability of shipowners; and the provisions of the principal act have here been materially altered by the act of 1862. Under the act of 1862, the owners of any ship, whether British or foreign, are not answerable in damages for any loss of life or personal injury to persons carried in the ship; for any damage or loss caused to any goods on board the ship; for any loss of life or personal injury by reason of the improper navigation of the ship caused to any person carried in any other ship; or for any loss or damage similarly caused to any other ship, or the goods on board of it, when such loss, or injury, or damage happens without their actual fault or privity, except as follows: Where loss of life or personal injury has occurred either alone or together with loss or damage to ships and merchandise, they are liable to the extent of £15 for each ton of the ship's tonnage; where there is loss or damage only of ships or merchandise, they are liable to the extent of £8 per ton. The tonnage, on account of which the liability in these cases is to be calculated, is, in the case of sailing-ships, the registered tonnage, and, in the case of steamships, the gross tonnage, without deduction on account of the engine-room; and the tonnage of foreign ships is to be estimated according to the rules of measurement laid down for British ships.

The act of 1854, however, provided that the owners of sea-going ships should be liable in respect of every loss of life, personal injury, loss of or damage to goods which may arise on distinct occasions, to the same extent as if no other loss, injury, or damage had arisen; and this provision is still in force. In cases of loss of life or personal injury, the act of 1854 empowers the Board of Trade to institute an inquiry, and provides in detail for the recovery of damages before the sheriff and a jury. The damages are to be assessed at £30 for each case of death or personal injury. These are to be a first charge upon the sum for which the owner is liable; they are to be paid to her Majesty's Paymaster-general, and to be distributed by him as the Board of Trade directs; the Board having power to direct payment to each person injured—or, in case of a death, to the husband, wife, parent, or child of the deceased—of such compensation, not exceeding the statutory amount, as may be thought fit. Until this inquiry has been instituted, or until the Board has refused to institute it, no person is to be entitled to sue in respect of any loss of life or personal injury. After its completion, any person injured, or the executor or administrator of any deceased person, who is dissatisfied with the statutory amount of damages, may, upon repayment to the owner of the sum he has already paid, bring his action for damages. But unless he recovers a sum exceeding double the statutory amount, he is liable in all the defendant's costs in the action; and the sum he recovers is payable only out of the residue (if any) of the aggregate amount for which the defendant is liable. Where several actions for compensation have been brought against the shipowner, whether for loss of life or personal injury, or for loss or damage of ships, boats, or goods, the Chancery Courts (or the Court of Session in Scotland) may, at his suit, determine the amount of his liability, distributing it rateably among the several claimants, and stopping all actions pending in other courts in relation to the same subject-matter.

Part X. of the act of 1854 lays down the legal procedure to be taken in cases arising under the act; and Part XI. deals with several miscellaneous matters of no general importance. The act of 1862 further provides that foreign ships within British jurisdiction shall be subject to the rules for preventing collisions applicable to British ships; and that upon agreement with any foreign country, these rules may, by order in Council, be made applicable to the ships of the said country, whether within British jurisdiction or not. Similarly, the provisions concerning salvage of life, applicable to British ships, may, by order of Council, be made applicable, in all British courts, to services rendered in saving life from the ships of a foreign country, whether within British jurisdiction or not. The act of 1862 also contains the law on the subject of delivery of goods and lien for freight (for which see *LIEN*).

MÉRIDA, a town of Venezuela, South America, capital of a province of the same name, about 60 miles south of the lake of Maracaybo. It was formerly the largest and one of the most important cities of Venezuela; but in 1812 it was almost wholly destroyed by an earthquake, from which misfortune it has somewhat recovered, and is again in a flourishing condition. Pop. 6000.

MÉRIMÉE, PROSPER, novelist, historian, and archaeologist, was born at Paris, September 26, 1803. His father, Jean François Leonore, was a painter of distinction, and secretary to the École des Beaux Arts. The son entered the College of Charlemagne, kept terms as a law-student, and

became early acquainted with English and Spanish literature. The influence of Shakspeare, Calderon, and Goethe was then making itself felt in France, and the Romantic School, headed by Victor Hugo, was contending for the possession of the stage against the classic traditions of Racine. M., a devotee of the new sect, published under a double disguise his first work, *Le Théâtre de Clara Gazul*, a collection of studies for the stage, professing to be translated from the Spanish by a certain Joseph L'Estrange. This work raised great expectations, which were never realised. M. did not become a dramatist, and one of these pieces failed when represented in 1850. His next publication, also pseudonymous, *La Gazula, by Hyacinthe Maglanovich*, was an effort to embody the spirit of the popular lays of Illyria and Montenegro. It was written to meet the then prevailing rage for Slavonic poetry, and the materials were taken at second-hand. It was, however, admired in Germany, and received the approval of Goethe. M. now became a regular contributor to the *Revue de Paris* and the *Revue des Deux Mondes*; and after one or two more anonymous efforts, signed his name to *Tamango*. After the revolution of July, he entered public life, and before long was made Inspector of Historical Monuments, and in that capacity visited many parts of France, publishing the results of his researches in a series of Reports. During all this time, he continued to write for his favourite *Revue* a series of romantic tales, in which terrible, almost repulsive subjects are handled with wonderful realistic power, and in a style singularly clear, condensed, and vigorous. This series, in which the *Etruscan Vase* and the *Capture of the Redoubt* are especially noteworthy, culminated in *Colomba* (1841), written by him when fresh from Corica, and its tales of vengeance. After this, his greatest and (with the exception of *Arsène Guillot*, and *Carmen*) his last romance, M. applied himself to historical researches. The *Conspiracy of Catiline* and the *Social War*, studies of Roman history, preliminary to a *Life of Cæsar*, on which he is said to have been occupied many years, appeared in 1844. In this year, he was elected to the chair in the Academy vacated by the death of C. Nodier. His *History of Dom Pedro the Cruel* (1848), dedicated to the Countess of Montijo, the mother of the Empress Eugénie, has been translated into English (1850), and reviewed in the *Edinburgh*. After the fall of the Orleans dynasty, he was placed on the Commission to draw up an inventory of the art treasures left by them in France. In 1854, he published his *False Demetrii*, an episode of early Russian history, the preface to which was written in prison, where he was sent for criticising, in the *Revue des Deux Mondes* (1852), the sentence passed on his old acquaintance, M. Libri (q. v.), a sentence which he tried to get reversed in the senate, June 11, 1861. M. has also translated from Pushkin and Nicolas Gogol. Among his latest writings may be mentioned an introduction to Marino Vetro's *Poetry of Modern Greece* (1855), and two brief notices in the *Revue des Deux Mondes* of Edward Ellice, M.P., and of Herbert's fresco-paintings for the House of Lords (1864). M. was made a senator in 1853; president of the commission for reorganising the Bibliothèque Impériale in 1858; Commander of the Legion of Honour, April 12, 1860. He is also one of the ten *membres libres* of the Académie des Inscriptions.

MESTRÉ, a town of Northern Italy, in the province of Venice, and 5 miles north-west of the city of Venice, on the margin of a lagoon. It is connected with Venice, Padua, and other places by railway. There are many villas around the town

and along the road to Padua, reaching almost to that city. M. has a considerable transit-trade. Pop. 8489.

METEORS. The whole subject of meteors was treated in the body of the work under the head of **AEROLITES**. The subject, however, has since occupied a great deal of attention, and there is at present a tendency on the part of astronomers and physicists to separate that class of meteors known as 'shooting-stars' from the group of *meteorolites* (which includes *aéro-siderites*, or masses of meteoric iron; *siderolites*, which are conglomerates of iron and stone; and *aérolites*, which are wholly of stone), on the grounds, that the most prominent appearances of the former are *periodic*, while the latter seem to occur at irregular intervals, and that the former have hitherto not been *proved* to leave any traces of their visit on the earth's surface. We are, however, hardly as yet in a position to decide as to the similarity or dissimilarity of the two classes of bodies.

Popular interest has been largely aroused respecting 'shooting-stars,' by reason of the brilliant display of them which took place on the night of November 13, 1866. This 'star-shower,' the grandest that has ever been observed in Britain, was confidently predicted, from the occurrence of a similar shower at the corresponding date in 1799, 1833, and 1834; and the extremely favourable state of the atmosphere rewarded those who were on the watch with a complete view of one of nature's most magnificent displays. The shower commenced about 11½ p.m., with the appearance at brief intervals of single meteors; then they came in twos and threes, steadily and rapidly increasing in number till 1h. 13m. a.m. on November 14, when no fewer than 57 appeared in one minute. From this time, the intensity of the shower diminished gradually, wholly ceasing about 4 a.m. The total number of meteors which at that time came within the limits of the earth's atmosphere was estimated at about 240,000, and the number seen at each of the several observatories in Britain averaged nearly 6000. This star-shower, like those of 1833 and 1834, seemed to proceed from the region of the heavens marked by the stars ζ and γ in the constellation Leo; and it has been shewn by astronomers that this was the point towards which the earth in her orbit was moving at the time; consequently, she had either overtaken the meteoric shower, or had 'met' it proceeding in a contrary direction. The meteors on that occasion presented the usual variety of colour, size, and duration; the great majority were white, with a bluish or yellowish tinge; a considerable number were red and orange; and a few were blue; many surpassed the fixed stars in lustre, and some were even brighter than Venus (the most brilliant planet as seen from the earth) at her maximum. Most of the meteors left trains of vivid green light 5"—15" in length, which marked their course through the heavens, and endured for 3" on an average, then becoming dissipated; though some of the trains were almost 40" in length, and remained in sight for several minutes. Professor Airy observed that the direction of the meteors' flight was little influenced by the earth's attraction.

On the morning of November 14, 1867, a star-shower equal in magnitude to that of 1866 was observed in France and America, but was almost wholly invisible in Britain, on account of the cloudy state of the atmosphere.

The brilliant display of 1866 gave a vigorous impulse to the astronomical investigation of shooting stars, and it is now generally agreed that the November meteors move in an orbit round the sun, inclined at about 7° to that of the earth,

and that, in all probability, this orbit forms a ring or belt of innumerable small fragments of matter, distributed with very variable density of grouping along it, thus corresponding so far to the Planetoid (q. v.) group between Mars and Jupiter. It is also agreed that the motion of this meteor ring round the sun is retrograde; that the earth's orbit at that point where she is situated on November 13—14, intersects this ring; and that, probably, in 1799, 1833—1834, and 1866—1867, it is the same group of meteors which has been observed; and the last-mentioned hypothesis has been made the foundation of a calculation of the probable orbit and periodic time of this meteor-ring. The fact that a November star-shower generally occurs for two years in succession, and then recurs at an interval of 32 or 33 years, seems to indicate that though the earth may pass through the meteor-orbit every year, the meteors are so grouped at intervals along the ring, and their periodic time differs so much from that of the earth, that it requires 32—33 years before this accumulating difference amounts to a complete revolution of either the earth or the ring, and a repetition of the star-shower becomes possible.

Professor Newton of Yale College, America, who entered into an elaborate investigation of the subject, concluded that the 5 possible periodic times (the earth's being taken as unity) of the meteor-ring were $2 \pm \frac{1}{33.33}$, $1 \pm \frac{1}{33.33}$, and $\frac{1}{33.33}$, and that of these, the fourth, $1 - \frac{1}{33.33}$, or 354.62 days, is the actual period of its revolution round the sun, and that, consequently, it has described 34 revolutions while the earth has described 33, the cycle of 34 meteor revolutions differing from 33 years by only 3.17 days; and in accordance with this estimate, he calculated its orbit and the approximate extent (seeing the meteor shower generally occurs in two successive years) of the meteor-group which produces the November showers. His conclusions have, however, been vigorously opposed by other eminent astronomers, such as Professor Adams (q. v.) and Mr Alexander Herschel, both of whom hold that the first four of the possible periods given by Professor Newton are impossible, and that the last, $\frac{1}{33.33}$ (i. e., that the meteor-ring makes $\frac{1}{33.33}$ of a solar revolution in a year, and one complete revolution round the sun in 33.25 years), is the correct estimate. If this view be correct, the meteor-group must be so much extended along its ring or orbit as to take more than a year to cross the earth's orbit, and a long time must necessarily elapse before a fair estimate of this extent can be obtained. A periodic time of 33½ years, and an orbit which at the same time approaches so near the sun as to intersect that of the earth, indicate a path of great ellipticity, akin to those of the comets; and the idea of the cometary nature of these meteors derives support from two remarkable facts, the one discovered by Schiaparelli of Milan, that this assumed orbit coincides very nearly with that of the great comet of 1862 (Professor Adams connects this comet with the August meteors), and the other by C. F. W. Peters of Altona, that it coincides with that of Tempel's comet.

Mr Alexander Herschel also maintains that the meteors are of recent origin, probably fragments from some of the great luminous bodies, and that though at present assembled in a comparatively dense group, the difference of their relative velocities will have the effect of gradually distributing them all over the meteoric ring, when a November shower will occur every year. Mr Herschel also carefully observed 20 meteors with the view of calculating their weight, from the rate of their motion and the amount of heat (as shewn by their brightness) evolved in the destruction of their velocity, by the

resistance of the atmosphere, and found their weight to vary from 30 grains to 7½ lbs.

The cause of the luminosity of meteors was long a point in dispute, the two chief suppositions being, that the resistance of the atmosphere to a body dashing through it at about 30 miles per second, generated so much heat as to produce ignition; while the other was the action of terrestrial magnetism. The point most strongly urged against the first supposition, by the supporters of the second, was, that the height at which meteors were occasionally seen rendered any action of the atmosphere impossible; but as this objection was founded on the purely hypothetical opinion that the atmosphere did not extend more than about 50 miles from the earth's surface, it was not very cogent. This problem was handled by Sir John Herschel in an able paper published in the *Edinburgh Review* (January 1848), in which he clearly shewed that the very high latent heat of the air in the higher and rarer parts of the atmosphere, would be sufficient to cause an enormous development of heat in the event of the air being compressed before a body advancing into it with a 'planetary' velocity. This opinion is now held by almost all eminent men of science. The enormous heat to which the meteor is thus subject produces incandescence, after which, with more or less facility, according to the nature of the materials of which the meteor is composed, the outer portion becomes liquid, and, by the powerful resistance of the air to the meteor's rapid course, is thrown off in a long stream, forming the tail, which, after rapidly losing its velocity, is precipitated to the earth as a fine dust like volcanic ash; while the meteor thus rapidly and constantly diminishing as it flies along in its headlong course, either becomes wholly dissipated into 'tail,' falls to the earth, or makes its way out beyond the limits of the earth's atmosphere, and continues its course. This supposition of exclusive atmospheric agency also gives a plausible explanation of the phenomenon of meteors 'bursting,' this being caused by the sudden heating and consequent expansion of the outer part, while the interior was still in the state of intense cold acquired while in interplanetary space.

While astronomers and physicists in general have been thus trying to reduce the phenomena of meteors to a system, their chemical brethren have not been idle. Public collections of meteoric bodies have been made at Vienna, the British Museum, Paris, Berlin; and private ones by Mr Greg of Manchester, Baron Reichenbach in Austria, and Professor Shepard in America; and opportunities have thus been afforded of determining the nature of their composition.

METHYLENE, BICHLORIDE OF ($C_2H_2Cl_2$), is an organic compound which has recently attracted much attention from its value as an anæsthetic agent. Dr Richardson, who has long been studying the physiological properties of the methyl-compounds, with the view of finding amongst them a safer compound than chloroform, believes, from his experiments on animals, that in the subject of this article he has found such a compound. As the deaths from chloroform may be computed, according to him, at one in 1500 administrations, it is obvious that there is reason for searching for a still safer anæsthetic agent. Dr Snow, as is well known, thought that he had discovered an almost positively safe agent in amylene ($C_{10}H_{16}$); but the value of more than 200 safe administrations was at once destroyed by two rapidly succeeding deaths; and hence a large number of successful cases of the new agent must be reported before it will displace chloroform from its present well-deserved position.

METHYLENE

In the article on METHYL (q. v.), we have shewn that the composition of hydride of methyl (or marsh gas) is expressed by C_2H_6 , which may be written C_2HHHH . Now, according to the theory of substitutions, one, two, three, or even all four of the atoms of hydrogen may be replaced by a corresponding number of atoms of chlorine. Thus, (a) if one atom of H be replaced by one atom of Cl, we have *chloride of methyl*, C_2H_5Cl ; (b) if two atoms of H are replaced by two atoms of Cl, the resulting compound is *bichloride of methylene*, $C_2H_4Cl_2$, the C_2H_4 here representing a new radical termed methylene, of which very little is known; (c) if three atoms of H are replaced by three atoms of Cl, the resulting compound is *trichloride of formyle*, C_2HCl_3 , or common chloroform, another radical, viz., formyle, C_2H , now appearing; (d) if the whole of the H is replaced by Cl, the resulting compound is *tetrachloride of carbon*, CCl_4 . We thus have four new bodies which may be constructed step by step out of hydride of methyl or marsh gas, and similarly, by starting with tetrachloride of carbon, the chemist may retrace the individual stages till he gets back to marsh gas. All these derivatives of marsh gas possess the power of producing anaesthesia when they are inhaled as vapour by men and animals. That the latter two—viz., chloroform and tetrachloride of carbon—possess this power, has been long known, Dr P. Smith having especially directed attention to the properties of the last-named compound; but that the first two also exert the same influence is a fact new to science, for which we are indebted to Dr Richardson. 'I discovered,' he observes, 'that chloride of methyl was a certain and gentle anaesthetic in July [1867] last, and this led me to hope that something more stable and manageable could be obtained—something that should stand between the chloride of methyl and chloroform. That substance is now found in the bichloride of methylene. That this compound would produce rapid, safe, and easy general anaesthesia, I discovered by experiment on August 30th of the present year.'—*Med. Times*, October 19, 1867.

It is a colourless fluid, having an odour like that of chloroform; and is pleasant to inhale, as it causes little irritation to the mucous membrane. It boils at 88° , and has a spec. gr. of 1.344, while that of its vapour is 2.937 (or nearly three times that of air). Hence, it boils at a lower temperature than other anaesthetics; while its specific gravity, both as a liquid and a vapour, is lower than that of chloroform, but much higher than that of ether; hence, from its easier evaporation, it requires more free administration than chloroform, and, from its greater vapour-density, it should be given less freely than ether. It mixes readily with absolute ether, and this combination yields a vapour containing corresponding proportions of each, their boiling-points only differing at most by 4° . It also combines with chloroform in all proportions. It should have a neutral reaction to test-paper. If a trace of acid be present—which is possible, but not probable—its inhalation might prove dangerous. To prevent decomposition, it should, like chloroform, be well guarded from the action of light.

Pigeons are the animals which Dr Richardson most employs for experiments on anaesthetic agents generally. They present various advantages over most other animals; one of the most important being that they die with singular readiness under the influence of these agents. On exposing three pigeons to the action of the vapour of a drachm of chloroform, bichloride of methylene, and tetrachloride of carbon, the peculiarity in the action of the bichloride is the absence, in the sleep it

produces, of the so-called second degree of narcotism. The bird glides from the first degree directly into the third, or that of absolute insensibility. The bichloride enters the circulation freely, and sustains the insensibility so well, that intervals of many minutes may be allowed to pass without readministration; while, from its being transformed altogether into vapour at a temperature lower than that of the body, it can be more readily eliminated from the system than chloroform, or tetrachloride of carbon, when its administration is withheld. On animals, it acts more evenly on the respiration and circulation than any other of the various substances which Dr Richardson has tried; and the only drawback, yet observed, is, that it sometimes produces vomiting; but this misadventure, so far as we know, has not yet been observed when it has been administered to the human subject, and pigeons are known to vomit on slight provocation. The numbers of the respirations and of the pulse rise and fall together, which 'is a good point, because there is no condition more perilous than disturbed balance of the circulating and respiratory systems.'

All anaesthetics given by inhalation after a certain dose destroy life; but that the destructive power of this new agent is less than that of either chloroform or tetrachloride of carbon, seems proved.

On trying the vapour upon himself, after ascertaining that it could be safely given to the lower animals, Dr Richardson inhaled it until it produced insensibility. 'I found the vapour very pleasant to breathe and little irritating, while drowsiness came on and unconsciousness without any noise in the head or oppression. I recovered also, as the animals seemed to recover, at once and completely. I felt as though I had merely shut my eyes, and had opened them again. In the meantime, I had, however, performed certain acts of a motor kind unconsciously; for I inhaled the vapour in the laboratory, and there went to sleep, but I awoke in the yard adjoining. This was on September 28th last, when I inhaled from a cup-shaped sponge. Since then, I have inhaled the vapour in smaller quantities from several instruments, with the effect of proving that there is little difference required for its administration and that of chloroform. A little more bichloride is required in the earlier stages than would be required if chloroform were being used, the fluid being more vaporisable. One drachm of bichloride to forty minims ($\frac{1}{4}$ of a drachm) of chloroform, represents the difference required; but when the narcotism is well set up, less of the bichloride is required to sustain the effect.'

The materials on which this article is based are taken from a lecture delivered by Dr Richardson on the 8th of October 1867. Since that date, he has tested the action of this compound on the human subject in five long and severe operations, four of which were cases of ovariectomy; and on the whole, the results have fully realised his expectations. One of the ladies operated on had once been under chloroform administered to her by the late Dr Snow; she was therefore able to compare the effects of the two, and she decided strongly in favour of the new agent, on the grounds, that 'it caused no sense of suffocation, no ringing sounds in the head, no nausea, and no after-depressing effect whatever, as chloroform in her case did; but it allowed her to drop into sleep precisely as in natural sleep, and to wake with all her senses aroused, as after natural sleep.' The quantity used averaged a little more than a fluid drachm every five minutes; two drachms being first used. The anaesthesia was, on an average, complete in five minutes, and was prolonged for six or seven minutes without readministration. In the *Medical Times and Gazette* for November 2, 1867,

it is reported that Mr Marshall, of Bedford Square, has administered this fluid in another case of ovariectomy, besides using it in several smaller operations; and Mr Gangee, of Birmingham, has administered it twice, one of his patients being an infant ten weeks old.* As yet, no bad symptoms have been recorded. Mr Spencer Wells has suggested for this new agent the name of 'Chloromethyl,' which will probably meet with general approval.

Chloride of Methyl, the first of the compounds derived by substitution from hydride of methyl, although not so likely to come into general medical use as bichloride of methylene, is likely, according to Dr Richardson, to obtain 'a most useful and important place in our remedial treasury.' Half an ounce of it, diluted with water, and with the addition of a little sugar, acts as a pleasant but potent intoxicator. In smaller doses, it might be useful as a soothing and refrigerating agent.

MEUDON, a town of France, in the dep. of Seine-et-Oise, 5 miles west of Paris, on the Versailles and Paris Railway. The *château*, approached by a fine avenue of four rows of lime-trees, was built by the side of an older *château*, the work of Philibert Delorme, by the Grand Dauphin, son of Louis XIV., in 1699. During the Revolution, it was converted into a factory for warlike engines, and surrounded with a permanent camp, to keep out spies. The *château*, as it exists at present, was fitted up for Marie Louise by Napoleon, in 1812. It has a fine terrace, gardens beautifully laid out, and commands a very fine prospect. The Forêt de Meudon is a favourite holiday resort of the Parisians. Near it has been erected an expiatory chapel, dedicated to Notre Dame des Flammes, marking the spot where a terrible railway accident occurred in May 1842, in which more than 100 persons were burned alive. Whiting is manufactured to a considerable extent, and there are numerous bleach-fields. Rabelais was curé of M. for a long time. The *château* has lately become a summer residence of Prince Napoleon. Pop. (1866) 5374.

MEU'LEBEKÉ, a town of Belgium, in the province of West Flanders, 20 miles south-west of Ghent, on the Mandel, a tributary of the Lys. Weaving is carried on, and there are several breweries. It is near a railway, which connects it with Bruges and other places. Pop. (1863) 8322.

MEXICO. After the declaration of war against Juarez by the French, they issued a proclamation to the Mexican people, April 16, 1862, setting forth that one of the objects of the contest was to rescue them from the tyranny of the President, and put the government of the country on a stable footing. Little faith, however, seems to have been put in these professions; and the invaders, though joined by Marquez, the military leader of the clerical party, met with little success till the arrival of General Forey with a reinforcement from France in September. Forey then took the command in chief, addressed a proclamation to the Mexicans, promising them perfect liberty in the choice of a new government in room of that of Juarez; and

in the spring of 1863, concentrated the French troops, and marched on Mexico. On his way, he took the strongly fortified city of Puebla after a two months' siege, capturing its defender, Ortega, and his whole force (May 18); and, Juarez having fled from the capital, and transferred the seat of his government to San Luis Potosi at their approach, the French entered Mexico on June 10. A fortnight afterwards, a provisional government, headed by General Almonte, was established, and an 'Assembly of Notables,' which was called (June 24) to deliberate upon the best form of government, decided in July, by a vote of 231 to 19, in favour of a 'Limited Hereditary Monarchy,' with a Catholic prince for sovereign, under the title of 'Emperor of Mexico,' and resolved in the first place to offer the crown to the Archduke Ferdinand Maximilian (q. v.) of Austria, failing whom, to request the good offices of the Emperor Napoleon in obtaining another monarch. That this resolution was the fruit of a general earnest wish on the part of the Mexican notables, the feeble and almost unwilling support most of them accorded to their chosen emperor after his desertion by the French, will not allow us to suppose; but, on the other hand, we have not the slightest reason for believing that anything approaching intimidation or undue influence was exercised by the French. Most of them doubtless argued that a government supported by France would be sufficiently powerful to maintain the country in a state of tranquillity, and in the hope of this long-wished-for result, cast in their lot for empire. These changes were, of course, vigorously protested against by the republican assembly at San Luis, and the two parties prepared with eagerness to try the fortune of war. On October 1, Forey departed from Mexico, and General Bazaine took the command of the French forces, and commenced the campaign with vigour. The result of the winter's struggle was that in spring the imperialists were in possession of the whole country, with the exception of the four northern provinces. On October 3, 1863, the Archduke Maximilian had given audience at his *château* of Miramar, near Trieste, to a deputation which was sent to offer him the crown, and had accepted it. On May 29, the emperor and empress landed at Vera Cruz, and on June 12, made their public entry into the capital; and soon after the middle of the year, the imperialists had gained possession of every state in the kingdom, Juarez fleeing in August to the United States. As small parties of the republicans still maintained a species of guerrilla warfare in various districts, Maximilian, on October 2, 1865, published a proclamation, menacing with death, according to the laws of war, all who were found in armed opposition to his government; the republic having ceased, not only by the express wish of the nation, but also by the expiry (November 22, 1864) of Juarez's term of office, and his flight beyond the frontiers; an amnesty, however, being accorded to such as submitted before November 15. In accordance with this edict, Generals Arteaga and Salazar, who were defeated and captured, October 13, were shot on the 21st; and many hundreds of captured republicans were dealt with under the terms of the same order.

This contest in M. had from the commencement excited the liveliest interest in the United States, though the civil war, raging there also, prevented any active interference in the affairs of its neighbour. A general impression existed that France had taken advantage of the troubles of the United States to establish its authority firmly on the American continent; and this belief, along with the violation of the 'Monroe doctrine' by the establishment of

* Since this article was written, additional cases have been described in the *Medical Times and Gazette*, of November 9, 1867. In one of these—in which a large fatty tumour, weighing 20 lbs., was removed from the abdomen—the patient was kept insensible for an hour and a quarter, and from 10 to 12 drachms were administered. In the *Lancet* for November 23, Mr Barnes of Liverpool records the case of its application to a boy, aged eight years, whose hip-joint was to be excised. The operation lasted 30 minutes, during the whole of which time the boy was in the deepest sleep.

MÉZIÈRES—MIDDLE LEVEL.

imperialism in M., induced the United States to give all their sympathy and diplomatic aid to Juarez and his supporters. In November 6, 1865, Secretary Seward forwarded a dispatch to Paris, in which it was stated that the presence of the French army in M. was a source of 'grave reflection' to the government of the United States, and that the latter could on no account allow the establishment of an imperial government, based on foreign aid, in M., or recognise in that country other than republican institutions. This dispatch led to an interchange of diplomatic notes during the following six months; the Americans holding firmly to their first statements, and even insinuating the probability of an armed interference on behalf of Juarez; till the French emperor, who was wearied with a contest so expensive and, though successful, so barren of lasting fruits, ultimately agreed, in the summer of 1866, to withdraw his troops from Mexico. The Belgian legion and some Austrian levies, however, were not included in this arrangement. Accordingly, from the autumn of 1866 till February 1867, the French troops by degrees evacuated M., and their departure was the signal for a fresh rising on the part of the Juarista. See MAXIMILIAN and JUAREZ in SUPPLEMENT.

MÉZIÈRES, a fortified town of France, capital of the dep. of Ardennes, on the right bank of the Meuse, on the isthmus of a promontory formed by the river, which washes its walls on two sides, and separates it from Charleville (q. v.). It was strongly fortified by Vauban, and is defended by a citadel. It communicates with Charleville by a suspension-bridge. In 1815, the town held out for two months against the Allies, who besieged it after the battle of Waterloo. Over the north aisle of the church is a bomb-shell, which has been sticking there ever since the town capitulated. In 1820, the Chevalier Bayard, with 2000 men, successfully defended it against 40,000 Spaniards under Charles V. The banner of Bayard is said to be still preserved in the Hôtel de Ville. Pop. (1866) 4651.

MEZQUITE, the name of two Mexican trees or shrubs, of the natural order *Leguminosæ*, suborder *Papilionaceæ*, bearing pods filled with a nutritious pulp. The COMMON M. (*Algarobia glandulosa*) is a small shrub, with stems often decumbent, and armed with strong straight spines. It is found in great profusion throughout vast regions, chiefly consisting of dry and elevated plains. In dry seasons, it exudes a great quantity of gum (*Gum Mezquite*), similar in quality to gum-arabic, which seems likely to become a considerable article of commerce, and which has begun to be exported to San Francisco from the Mexican ports on the Pacific.—The CURLY M., or SCREW M. (*Strombocarpa pubescens*), also called SCREW BEAN and TOURNIL, although only a shrub or small tree, is of great value in the wild and desert regions of the western part of North America, where it occurs along with willow-bushes near springs of water. Its wood is used as fuel, and the pulp of its pods for food. The pods are spirally twisted into compact rigid cylinders, from an inch to an inch and a half in length.

MEZZOJU'SO (Arab. *Mensh-Jussuf*, village of Joseph), a town of Sicily, in the province of Palermo, 18 miles south-south-east of Palermo city. It is one of the four colonies of Albanians, who, on the death of Scandarbeg, in the 15th c., fled to Sicily, to avoid the oppression of the Turks. They preserve their language to a great extent, and follow the Greek ritual, their priests being allowed to marry; but, except on fête-days, they are not to be distinguished in feature or dress from the peasantry of the rest of Sicily. Pop. (1861) 5686.

MGLIN, a town of Russia, in the government of Tchernigov, 125 miles north-north-east of the town of Tchernigov. There is a large cloth-factory, and a considerable number of German families. Pop. 8045.

MHENDIGU'NJ, a town of British India, in the territory of Ouda, 90 miles south-east of Lucknow, 3 miles south of the right bank of the river Saec. It is a busy, thriving place, with a pop. estimated at 20,000.

MHOW, a town of British India, in the territory of Indore, 13 miles south-west of the town of Indore, near the Vindhyan Mountains, on an eminence on the Gumber river. Near it are the cantonments, which have altogether the appearance of a European town, having a church with steeple on an eminence, a spacious lecture-room, a well-furnished library, and a theatre. They are situated at an elevation of 2019 feet above the sea, and are occupied by a considerable force. On the 1st July 1857, the sepoya mutinied here, during the great rebellion of that year.

MIA'VA, a market-town of North-west Hungary, on the Miava, an affluent of the Morava, 48 miles east-north-east of Presburg city. There are manufactures of woollen cloth and bagging, and hemp and flax are cultivated. Pop. 9269.

MICROZA'MIA, a genus of plants of the natural order *Cycadaceæ*. They are widely diffused over Australia. The fronds resemble those of palms, and are used in the Roman Catholic Church on Palm Sunday. The underground stem is large and turnip-like, but covered with scales or leaf-scars, and contains a substance resembling tragacanth. The nuts of *M. spiralis* are edible, but are only used in times of scarcity.

MIDDLE LEVEL. Under the heading BEDFORD LEVEL, a remarkable district, covering 400,000 acres, is described, bounding the Wash on all sides except seaward, extending landward nearly to Brandon, Cambridge, Peterborough, and Bolingbroke, and embracing portions of the six counties of Northampton, Huntingdon, Cambridge, Lincoln, Norfolk, and Suffolk. It nearly coincides in area with what is popularly known as the Fens. The whole region was, centuries ago, converted into an unprofitable marsh by repeated incursions of the sea, coupled with obstructions to the outward flow of the rivers Nene, Cam, Ouse, Welland, &c. Vast operations have been carried on ever since the time of Charles I., by digging new channels and outfalls, and employing windmills and steam-engines to pump the water from the marshes and ponds into these artificial channels. The Bedford Level is divided into the *North*, the *Middle*, and the *South Levels*, managed by commissioners, whose powers are derived from special acts of parliament. The improved value of the land is the fund out of which the expense of the engineering works is defrayed. It was in one of these districts (the Middle Level, between the Nene and the Old Bedford River) that an irruption took place in 1862, which strikingly illustrates the dependence of the safety of the whole region on well-formed and well-maintained embankments. There was a sluice, called St Germain's Sluice, situated at the confluence of the Middle Level main outfall drain with the river Ouse, near the upper end of another artificial channel, known as the Eau Brink Cut. The drain was made in 1847, and was enlarged ten years afterwards to a bottom-width of 48 feet, a side-slope of 2 to 1, and a level of 7 feet below low-water spring-tide in the river; the rise of high-water spring-tide at that point was 19 feet, and the

sill of the sluice was 6 feet below low-water spring-tide.

On the 4th of May 1862, this sluice gave way without the slightest warning; the tidal waters undermined the brickwork, and formed a hole in the bed of the river, into which the works of the sluice sank. The tidal waters rushed up the opening, and ebbd and flowed throughout a distance of 20 miles. The commissioners of the Middle Level applied to Mr Hawkshaw, the engineer, to devise means for repairing the disaster. An earth and cradle-dam was attempted to be thrown across the drain, at about 500 yards from the fallen sluice; but this was relinquished in favour of a permanent coffer-dam of pile-work, at a distance of half a mile from the sluice; and after incessant exertions from May 16 to June 19, the tidal waters were at length effectually shut out by a strong dam. The failure of the St Germain's Sluice was not the only irruption that had to be battled with; eight days after that failure, under the pressure of a high spring-tide, the west bank of the drain gave way, on May 12, at a point about 4 miles from the sluice; the bank had been built only to resist upland waters, and not a rush and a pressure of the sea. The rupture carried away 70 yards of the bank, scouring out a hole 10 feet deep at the spot, and admitting a rush of water which covered 6000 acres of fertile land to a depth of 2 or 3 feet, increased at successive high-tides to 10,000 acres.

When the finishing of the dam had enabled Mr Hawkshaw to shut out the tidal waters, means had to be devised for getting rid of the flooding waters, and providing an outlet for the usual rivers and land-drainage of the Middle Level. It was resolved to utilise some of the old outlets at other spots, and to supplement their action by enormous syphons, placed over the coffer-dam. Sixteen syphons were provided. They were made of cast iron, 3 feet 6 inches internal diameter, and somewhat over 1 inch thick; they rested on the top of the dam, and on inclined framework supported by piles at the sides. The valves were so arranged, that the syphons could be put in operation, either by exhausting the air or by filling them with water. When only six of the syphons were in position, they carried 50,000 gallons of water per minute over the dam.—For more minute details of the dam and the syphons, see Mr Hawkshaw's paper read before the Institute of Civil Engineers in 1863.

There are large items both of cost and of compensation in works of this kind. Nearly the whole of the Middle Level is 15 feet below high-water spring-tides; it is difficult to keep out the sea-water, and at the same time to preserve an outlet for the land-water, especially Whittlesea Mere; there are 130,000 acres to be drained somehow or other; but as the land is rich for farming, the commissioners, in past years, did not hesitate to spend £400,000 on 11 miles of drain, and £30,000 on the sluice. The drain runs through a district called *Marshland*, between Lynn and Wisbeach; and as the bursting of the bank caused this district to be deluged with water, the commissioners have had to compensate the *Marshland* farmers and others; the amount of this compensation has been frequently litigated between 1862 and 1867. As concerns the land itself, it is found to be more fertile after such inundations than before, owing to the amount of silt deposited on the fields. After repairing the breach in the bank, the 10,000 inundated acres were drained without much difficulty, through the *Marshland*, *Smeeth*, and *Fen* drain, and the *Marshland* sewer; the syphons are permanent channels, to carry off the usual land-waters regularly. The syphons were subjected to a severe trial in January 1867, by the

ice which accumulated around their lower ends; but iron gratings effectually resisted the entrance of the ice into the syphons.

MIKANIA, a genus of plants of the natural order *Composita*, nearly allied to *Eupatorium* (q. v.). The heads of flowers are 4-flowered, and have four involucre leaves. *M. officinalis* is a Brazilian species, with erect stem, and heart-shaped leaves, abounding in a bitter principle and an aromatic oil, and valuable as a tonic and febrifuge. *M. Guaco* and *M. opifera*, also natives of the warm parts of South America, are among the plants which have acquired a high reputation—deserved or undeserved—for the cure of snake-bites. They are twining herbaceous plants. *M. Guaco* is remarkable for the large indigo-blue spots on the under side of its ovate leaves. The mode of using this plant, which is one of those called **GUACO**, or **HUACO**, by the Indians, is by dropping the juice of the fresh leaves into the wound made by a serpent; or little cakes are formed of the bruised plants, which are said to retain their power for a long time. The whole subject requires investigation.

MIKLOS (Sr) **TOROK**, a town of Hungary, in the county of Henee, near the Theiss, about 70 miles south-east of Pesth, with which it is connected by railway. Pop. 10,437, chiefly employed in rearing horses and cattle, and in fishing.

MINDSZENT, a town of Hungary, in the county of Csongrad, near the left bank of the Theiss, and just below the mouth of the Saros, 19 miles north from Szegedin. Pop. 9163.

MINE'O, a town of the island of Sicily, in the province of Catania, 82 miles south-west of Messina. It is supposed to occupy the site of the ancient *Mena*, founded by Ducetius, 459 B. C. Pop. (1861) 3547.

MINK (*Mustela lutreola*), a species of weasel, inhabiting the northern parts of Europe and Asia; very similar to which in characters and habits is another species, by some regarded as only a variety of the same, the *M.* or *VISON* (*M. vison*) of North America, abundant in almost every part of that continent. Both inhabit the neighbourhood of streams, lakes, and marshes; have semi-palmated feet, are expert swimmers and divers, and prey on fishes, frogs, and other aquatic animals, as well as on birds, rats, mice, &c. They are covered with a downy fur, interspersed with longer and stronger hairs: the colour is brown, with more or less of white on the under parts. The American *M.* is generally larger than that of the Old World, being often more than eighteen inches from the nose to the root of the tail, whilst the latter is seldom more than twelve. It has also a more bushy tail. It is very active and bold, and often commits great depredations in poultry-yards, carrying off a fowl with great ease. Unlike most of its congeners, it is easily tamed, and becomes much attached to those who care for it. In domestication, it ceases to regard the inmates of the poultry-yard as prey. It emits an unpleasant odour only when irritated or alarmed. The fur of the *M.* is valuable.

MIRTA, a town of India, in the Rajpoot state of Jodhpur, stands on high ground near the source of a tributary of the Luni, 230 miles south-west of Delhi. *M.* is supplied with good water from three large tanks. Pop. estimated at 25,950.

MISHMEE BITTER, the root of *Coptis Teeta* (see **COPTIS**), a plant found in the mountainous regions on the borders of India and China; of the same genus with the Golden Thread of the northern parts of the world, and not unlike it. The root is in much use and esteem in some parts of the East

as a stomachic and tonic, and has begun to be known in Europe.—The root of *C. trifoliata* is also used as a bitter.

MISILMERI (corrupted from *Menzil-al-Amir*, Village of the Emirs), a town of the island of Sicily, in the province of Palermo, 7 miles south-east of Palermo city. It is a straggling, poverty-stricken town. It was at M. that Garibaldi, in May 1860, joined the Sicilian insurgents; and it was by a short cut from M. to Palermo, through the Pass of Mezzagna, that he advanced on the latter city and took it by a *coup de main*. M. is a notorious harbour of banditti. Pop. (1861) 7231.

MITTWEIDA, a town of Saxony, in the circle of Zwickau, 35 miles south-east of Leipzig. For centuries, M. has been noted for its industry. The principal branches of industry are spinning, cotton-weaving, manufacture of fustian, &c., together with dyeworks and bleach-fields. Pop. (1864) 8285.

MOFFAT, ROBERT, a distinguished missionary, was born at Inverkeithing, Fifeshire, Scotland, towards the close of last century. Having resolved to become a missionary to the heathen, he offered his services to the London Missionary Society, was accepted, and sent by them to South Africa. Arriving at Cape Town in 1817, he immediately proceeded beyond the boundaries of Cape Colony to Namaqualand, where he entered upon his labours at the kraal of Africaner, a chief whose name had long been a terror to the people of the neighbouring districts of the colony, on account of the audacious raids which he made among their settlements, and his ferocious character, but who had lately become a convert to Christianity, and now shewed a warm desire for its promotion. Here M. laboured for three or four years with great success, Christianity and civilisation advancing together. But the situation, on account of the drought and sterility of the country, and its very thinly scattered population, being unsuitable for a principal mission-station, he set out in search of a better locality, and laboured at several stations in succession in the countries to the north and north-east of Cape Colony. Wherever he went, the gospel was gladly received by some of those who heard it, and in some places by many. In every place he also guided the people in the arts of civilised life. He made several missionary tours, and his adventures were very remarkable, and are graphically described in his work, *Missionary Labours and Scenes in Southern Africa* (Lond. 1842), which he wrote and published during a visit of several years to Britain, rendered necessary by the state of his health. This publication, and his many speeches and sermons during his stay in his native country, did much to animate missionary zeal, and to direct it towards Africa. In 1842, M. returned to his labours in that country. His daughter is the wife of the still more celebrated missionary and traveller, Dr Livingstone (q. v.).

MOGUER (Arab. 'caves,' of which there are many in the neighbourhood), a town of Spain, in the province of Huelva, 43 miles west-south-west of Seville, rises gently above the Rio Tinto, near the mouth of which is its port, Palos. The streets are generally broad and straight, but both the town and castle are much dilapidated. The old Franciscan convent was ordered in 1846 to be preserved as a national memorial, but it is now fast going to ruin, and the wood of the cells stripped off. It was here, in 1494, that Columbus, craving charity, was received by the prior, Juan Pérez de Marchena, by whose influence he was enabled to prosecute his discoveries, setting out from the port of Palos on August 3, 1492. It was to this port also that he returned, March 15, 1493, after having accomplished

the great end of his expedition. Here likewise did Cortes land in May 1528, after the conquest of Mexico, and lodged in the same convent which gave shelter to Columbus. Palos is now a poor decayed fishing-port. M. has some trade in wine and fruit. Pop. 6592.

MOHAMMEDAN SECTS. 'My community,' Mohammed is reported to have said, 'will separate itself into seventy-three sects; one only will be saved, all the others shall perish.' This prophecy has been largely fulfilled. Even during the illness, and immediately after the death of the founder, many differences of opinion arose among his earliest adherents. We have endeavoured to shew, both under **KORAN** and **MOHAMMEDANISM**, how the fundamental book of Islam left certain points undecided by the very fact of its poetical wording, and how, further, the peculiarity of the Arabic idiom at times allowed many interpretations to be put upon one cardinal and dogmatic sentence. To add to this uncertainty, a vast number of oral traditions sprang up and circulated as an expansive corollary to the Koran. Political causes soon came to assist the confusion and contest, and religion was made the pretext for faction-fights, which in reality had their origin in the ambition of certain men of influence. Thus 'sects' increased in far larger numbers even than the Prophet had foretold, and though their existence was but short-lived in most instances, they yet deserve attention, were it only as signs and tokens of the ever-fresh life of the human spirit, which, though fettered a thousand times by narrow and hard formulas, will break these fetters as often, and prove its everlasting right to freedom of thought and action.

The bewildering mass of these currents of controversy, has by the Arabic historians been brought under four chief heads or fundamental bases. The first of these relates to the divine attributes and unity. Which of these attributes are essential or eternal? Is the omnipotence of God absolute? If not, what are its limits? Further, as to the doctrine of God's predestination and man's liberty—a question of no small purport, and one which has been controverted in nearly all 'revealed' religions—How far is God's decree influenced by man's own will? How far can God countenance evil? and questions of a similar kind belonging to this province. The third is perhaps the most comprehensive 'basis,' and the one that bears most directly upon practical doctrines—viz., the promises and threats, and the names of God, together with various other questions chiefly relating to faith, repentance, infidelity, and error. The fourth is the one that concerns itself with the influence of reason and history upon the transcendental realm of faith. To this chapter belong the mission of prophets, the office of Imam, or Head of the Church, and such intricate subtleties as to what constitutes goodness and badness; how far actions are to be condemned on the ground of reason or the 'Law;' &c.

One broad line, however, came to be drawn, in the course of time, among these innumerable religious divisions, a line that separated them all into orthodox sects and heterodox sects; orthodox being those only who adopted the oral traditions, or Sunna (see **SUNNITES**).

Much more numerous than the orthodox divisions are the heterodox ones. Immediately after Mohammed's death, and during the early conquests, the contest was chiefly confined to the question of the Imam. But no sooner were the first days of warfare over, than thinking minds began to direct themselves to a closer examination of the faith itself, for which and through which the world

was to be conquered, and to the book which preached it, the Koran. The earliest germs of a religious dissension are found in the revolt of the Kharejites against Ali, in the 37th year of the Hedjrah; and several doctors shortly afterwards broached heterodox opinions about predestination and the good and evil to be ascribed to God. These new doctrines were boldly, and in a very advanced form, openly preached by Wâsil Ibn Atâ, who, for uttering a moderate opinion in the matter of the 'sinner,' had been expelled from the rigorous school of Basra. He then formed a school of his own—that of the Separatists or Motazilites (q. v. in SUPPLEMENT), who, together with a number of other 'heretical' groups, are variously counted as one, four, or seven sects.

We now come to the second great heretic group, the Sefatians. The Sefatians (attributionists) held a precisely contrary view to that of the Motazilites. With them, God's attributes, whether essential or operative, or what they afterwards called declarative or historical, i. e., used in historical narration (eyes, face, hand), anthropomorphisms, in fact, were considered eternal. But here, again, lay the germs for more dissensions and more sects in their own midst. Some taking this notion of God's attributes in a strictly literal sense, assumed a likeness between God and created things; others giving it a more allegorical interpretation, without, however, entering into any particulars beyond the reiterated doctrine, that God had no companion or similitude. The different sects into which they split were, first, the Asharians, so called from Abul Hasan al Ashari, who, at first a Motazilite, disagreed with his masters on the point of God's being bound to do always that which is best. He became the founder of a new school, which held (1) that God's attributes are to be held distinct from his essence, and that any literal understanding of the words that stand for God's limbs in the Koran is reprehensible. (2) That predestination must be taken in its most literal meaning, i. e., that God preordains everything. The opinions on this point of man's free will are, however, much divided, as indeed to combine a predestination which ordains every act with man's free choice is not easy; and the older authors hold it is well not to inquire too minutely into these things, lest all precepts, both positive and negative, be argued away. The middle path, adopted by the greater number of the doctors, is expressed in this formula: There is neither compulsion nor free liberty, but the way lies between the two; the power and will being both created by God, though the merit or guilt be imputed to man. Regarding mortal sin, it was held by this sect, that if a believer die guilty of it without repentance, he will not, for all that, always remain a denizen of hell. God will either pardon him, or the Prophet will intercede on his behalf, as he says in the Koran: 'My intercession shall be employed for those among my people who shall have been guilty of grievous crimes;' and further, that he in whose heart there is faith but of the weight of an ant, shall be delivered from hell-fire. From this more philosophical opinion, however, departed a number of other Sefatian sects, who, taking the Koranic words more literally, transformed God's attributes into grossly corporeal things, like the Mosshabehites, or Assimilators, who conceived God to be a figure composed of limbs like those of created beings, either of a bodily or spiritual nature, capable of local motion, ascent, or descent, &c. The notions of some actually went so far as to declare God to be 'hollow from the crown of the head to the breast, and solid from the breast downward; he also had black curled hair.' Another sub-

division of this sect were the Jabarians, who deny to man all free agency, and make all his deeds dependent on God. Their name indicates their religious tendency sufficiently, meaning 'Necessitarians.'

The third principal division of 'heretical sects' is formed by the Kharejites, or 'Rebels' from the lawful Prince—i. e., Ali—the first of whom were the 12,000 men who fell away from him after having fought under him at the battle of Seffein, taking offence at his submitting the decision of his right to the califate (against Moawiyah) to arbitration. Their 'heresy' consisted, first, in their holding that any man might be called to the Imamate though he did not belong to the Koreish, nor was even a freeman, provided he was a just and pious man, and fit in every other respect. It also followed that an unrighteous Imam might be deposed, or even put to death; and further, that there was no absolute necessity for any Imam in the world.

Of the fourth principal sect, the Shiites, or 'Sec-taries,' the followers of Ali Ibn Abi Taleb, we have spoken under that special heading.

It remains only to mention a few of the many pseudo-prophets who arose from time to time in the bosom of Islam, drawing a certain number of adherents around them, and threatening to undermine the church founded by Mohammed, by either declaring themselves his legal successors, or completely renouncing his doctrines. The first, and most prominent among these, was Moesaylima (q. v. in SUPPLEMENT). Next to him stands Al-Aswad, originally called Aihala, of the tribe of Ans, of which, as well as of that of a number of other tribes, he was governor. He pretended to receive certain revelations from two angels, Sohaik and Shoraik. Certain feats of legerdemain, and a natural eloquence, procured him a number of followers, by whose aid he made himself master of several provinces. A counter-revolution, however, broke out the night before Mohammed's death, and Al-Aswad's head was cut off; whereby an end was put to a rebellion of exactly four months' duration, but already assuming large proportions. In the same year (11 Hedjrah), but after Mohammed's death, a man named Toleiha set up as prophet, but with very little success. He, his tribe, and followers were met in open battle by Khalid, at the head of the troops of the Faithful, and being beaten, had all finally to submit to Islam.

A few words ought also to be said regarding the 'Veiled Prophet,' Al-Mokanna, or Borkai, whose real name was Hakem Ibn Hashem, at the time of Al-Mohdi, the third Abbaside calif. He used to hide the deformity of his face (he had also but one eye) by a gilded mask, a circumstance which his followers explained by the splendour of his countenance being too brilliant (like that of Moses) to be borne by ordinary mortals. Being a proficient in jugglery besides, which went for the power of working miracles, he soon drew many disciples and followers around him. At last he arrogated the office of the Deity itself, which by continual transmigrations from Adam downwards, had at last resided in the body of Abu Moslem, the governor of Khorassan, whose secretary this new prophet had been. The calif, finding him growing more and more formidable every day, sent a force against him, which finally drove him back into one of his strongest fortresses, where he first poisoned and then burned all his family; after which he threw himself into the flames, which consumed him completely, except his hair. He had left a message, however, to the effect that he would reappear in the shape of a gray man riding on a gray beast, and many of his

followers for many years after expected his reappearance. They wore, as a distinguishing mark, nothing but white garments. He died about the middle of the 2d c. Hedjrah.

Of the Karmathians and the Ismailis, we have spoken under these special headings. We can scarcely enumerate among the prophets Abul Teyeb Ahmed Al-Motanebbi, one of the most celebrated Arabic poets, who mistook, or pretended to mistake, his poetical inspirations for the divine afflatus, and caused several tribes to style him prophet, as his surname indicates, and to acknowledge his mission. The governor of his province, Lalá, took the promptest steps to stifle any such pretensions in the bud, by imprisoning him, and making him formally renounce all absurd pretensions to a prophetic office. The poet did so with all speed. He was richly rewarded by the court and many princes for his minstrelsy, to which henceforth he clung exclusively; but the riches he thus accumulated became the cause of his death. Robbers attacked him while he was returning to his home in Kufa, there to live upon the treasure bestowed upon him by Adado'ddawla, Sultan of Persia.—The last of these new prophets to be mentioned is Baba, who appeared in Amasia, in Natolia, in 638 Hedjrah, and who had immense success, chiefly with the Turkmans, his own nation, so that at last he found himself at the head of nearly a million men, horse and foot. Their war-cry was, God is God, and Baba—not Mohammed—is his prophet. It was not until both Christians and Mohammedans combined for the purpose of self-defence, that this new and most formidable power was annihilated, its armies being routed and put to the sword, while the two chiefs were decapitated by the executioner.

MOLESKIN AND CORDUROY are varieties of FUSTIAN (q. v.), a term which is used in a generic sense to include also velveteen, velveret, thick-set, thick-set cord, beaverteen, and other stout cotton cloths for men's apparel—a class of goods largely manufactured in Lancashire. The general structure of these fabrics is described under FUSTIAN and VELVET. They are, in point of fact, all of the nature of velvet, with a *nap* or *pile* on the surface, and most of them are twilled.

When cloth of this kind leaves the loom, its surface is covered with loops like Brussels carpet, and these are then cut open with a ripping-knife of a peculiar shape, which the operatives learn to use with great dexterity. The hairy and uneven appearance which the cloth acquires in this operation is subsequently improved by the shearing process. The cloth is next steeped in hot water, to get rid of the paste used in dressing the yarn, and is then ready to be passed through the brushing or teasing machine, which consists of blocks of wood with concave surfaces covered with card-brushes, working backwards and forwards in a lateral direction against wooden rollers, encased in tin-plate, over which the cloth passes. The tin-plate is made rough with the burs of punched holes. In the next operation, the fustian is singed by passing the nap side quickly over a red-hot metal cylinder. The brushing and singeing are repeated three and occasionally four times, to give the cloth a smooth appearance. It is then washed, bleached with chloride of lime, and dyed—usually of some shade of olive, slate, or other quiet colour.

The different names given to fustian cloths depend upon their degree of fineness, and the manner in which they are woven and finished. Thus, smooth kinds, of a strong twilled texture, are called *mole-skins* when shorn before dyeing, and *beaverteens* when cropped after dyeing. Corduroy, or king's cord, is produced by a peculiar disposition of the pile-

threads. In all fustians, there is a warp and weft thread, independent of the additional weft-thread forming the pile; but in corduroys, the pile-thread is only 'thrown in' where the corded portions are, and is absent in the narrow spaces between them.

Until a comparatively recent period, the quantity of fustian cloths annually consumed in the British Islands must have been very large, but the increased price of cotton, and the introduction of cheap woollen fabrics, have now very much curtailed the use of them. They are still, however, largely worn by certain classes of mechanics and labourers.

MO'LOCH, a genus of saurian reptiles, of the family *Agamida* (see AGAMA). *M. horridus*, an Australian species, is perhaps the most ugly and repulsive in appearance of all the saurian tribes. The whole surface of the body is covered with

Moloch horridus.

irregular plates and strong sharp spines; the upper surface of the head is crowned with two very large spines; and on the back of the neck are large rounded protuberances, covered with granular scales and spines. The *M.* is, however, a perfectly inoffensive creature.

MOLTKE, HELLMUTH, FREIHERR VON, Lieutenant-general and chief of the general staff in Prussia, who planned the Prussian campaign of 1866 against Austria. He belongs to an old family, who had their seat for centuries in Mecklenburg, where *M.* was born, 26th October 1800. Soon after his birth, his father, a military officer, left Mecklenburg, and acquired an estate in Holstein, where *M.* spent the first twelve years of his life, whence some biographers name Holstein as his native land. He and his brother were sent to the military academy in Copenhagen, where iron discipline and military frugality laid the foundation of his later character. In 1822, he entered the Prussian army as cornet. His parents having by this time lost all their fortune, he was left without any means whatever, and had to undergo many hardships to maintain himself in his position, from the very modest pay the Prussian officers receive; yet he managed to save enough to take lessons in modern languages, which afterwards proved of great advantage to him. His eminent abilities soon procured him a place in the general staff. The time between 1835 and 1839, he spent in Turkey and Asia Minor, whither he was sent by the Prussian government to report on the war between that country and Mehemet Ali. Several anonymous publications of his, descriptive of the country and the war, are worthy of notice. After his return, he rapidly advanced through the different stages to the rank of general, continuing, however, on the general staff.

As Germany is indebted to Count Bismark for the political and diplomatic part of the work of the

recent reorganisation, so she is to M. for the strategical. The general nature of his plan, and how well it attained the end in view, may be seen in the description of the campaign in the article GERMANY, in the SUPPLEMENT.

M. is a man of great modesty and simplicity; he is reserved, and so little given to talk, that he has acquired the surname of 'the Silent.' The same composure and equanimity that he possesses in council, he also preserves in the heat of the battle. He is a real general, whom the army regards with love, respect, and confidence.

MOMBA'SSA, or **MOMBAZ**, a seaport town of East Africa, in the territory of the Sultan of Zanzibar, on a small coralline island off the coast, in the middle of an estuary formed by two small rivers, in lat. 4° 4' S., and long. 39° 43' E., about 150 miles north of Zanzibar island. The shores of the island are rocky and abrupt; and although the channel may be forded at low water, the attempt is attended with danger. The town has the usual Arab characteristics of ruin, neglect, and filth in a striking degree. The only object of interest is an extensive fort, built on a rock, cut perpendicularly, in 1596, by the Portuguese, and restored by them in 1636, as an inscription over the principal gateway indicates. It is a work of considerable pretension, with upwards of one hundred guns in position, but in a ruinous condition. The inhabitants, the majority of whom are sunk in abject poverty, mostly live in wretched hovels, scattered among what remains of the once magnificent buildings. The town and island of M., as well as the surrounding district, is inhabited by the Wanika tribe. The harbour is still good, and is commodious and safe. M. was visited by Vasco da Gama in 1497, when he found it to be a large and very prosperous town. It was held by the Portuguese during the greater part of the period from 1529 to 1720, when it appears to have become independent. The English held it from 1824 to 1826, when they resigned it. Since then, it appears to have been possessed by the Sultan of Zanzibar, and apparently is considered a place of some importance. Burton says that the inhabitants of M. 'are justly taxed with pride, bigotry, evil-speaking, insolence, turbulence, and treachery by other Arabs.'

MONASTIER, a seaport town of North Africa, in the dominion of Tunis, 80 miles south-south-east of the city of that name, on the Gulf of Sidra. Woollen and camel fabrics are manufactured, and there is some maritime trade. Pop. 12,000.

MONSELICÉ, a walled town of North Italy, 13 miles south-east of Padua, on the canal of Monselice, which extends from Padua to Este. M. was a place of importance in the middle ages. It has several silk-mills. Pop. 8160.

MONTBRISON, a town of France, capital of the dep. of Loire, 37 miles south-west of Lyon, on the Vizezy, a feeder of the Loire, stands at the base of a lofty and precipitous rock. In the vicinity are mineral springs. Pop. (1866) 5854.

MONT-DE-MARSAN, a town of France, capital of the dep. of Landes, at the junction of two streams—the Midou and Douze—which, when united, take the name of Midouze, and join the Adour. It is 65 miles south of Bordeaux, with which and with other places it is connected by railway. The town has of late years made great progress. It has a communal college, and mineral warm baths. There are manufactures of common woollen cloths, blankets, sail-cloth, and leather. Pop. (1866) 7008.

MOQUEGUA, a town of Peru, capital of a province of the same name, 68 miles north-west of Tacna, on the great route west of the Cordilleras.

In the province are many large vineyards, which produce great quantities of wine and brandy. Pop. 9000.

MORADABA'D, a town of British India, capital of a district of the same name, is situated on a slightly elevated ridge between the Ramgunga and the Ganges, 90 miles east-north-east of Delhi. There is a large jail, capable of holding 1800, for native convicts. West of the town, and separated from it by the jail, are the cantonments for the troops, agreeably situated amid luxuriant trees; the chief duty of the troops is to guard the great assemblage of convicts. Pop. said to be 57,414.

MORELIA, or **VALLADOLID**, a town of Mexico, capital of the state of Michoacan, in a fine valley, surrounded by high mountains, 125 miles west-north-west of Mexico. There is a magnificent aqueduct for the supply of water. It was the birthplace of Iturbide, the short-lived emperor of Mexico. Pop. 25,000.

MORELLA (anc. *Castra Ælia*, the winter-quarters of Sertorius), a town and important fortress of Spain, in the province of Castellon, about 80 miles north of Valencia. M. was the chief stronghold of Cabrera, who scaled the castle by ropes furnished by a partisan within, on the night of the 26th January 1838. It was retaken in 1840 by Espartero, after a brave defence. There are some interesting Roman and Moorish antiquities. Pop. 6211.

MOSAIC WOOL, or **WOOL MOSAIC**, is a remarkable application of the principle of mosaic-work to the production of woollen or worsted rugs and carpets, having a definite design or pattern, independent of the ordinary processes of printing and weaving. Many attempts in this direction have been made, chiefly on the continent; but the most successful is that of Messrs Crossley, in whose extensive carpet factory at Halifax the mosaic wool is produced as a regular department of manufacture.

In the first place, well-spun worsted threads are dyed to every colour and almost every shade or tint, amounting to a hundred varieties in all. An artist prepares a full-sized drawing of the pattern or design, ruled all over with cross-lines; this is copied on lined paper by girls, each of whom takes as much of the pattern as will fill a square foot. A workman (or woman) having a good eye for colour, examines each square piece of drawing in detail, and selects the proper colour of thread suitable to every portion of it; the threads are a little over 200 inches long each, or about 17 feet, and are numerous enough to pack closely together into a mass of one square foot in width and depth. A strong iron framework, 17 feet long, is so arranged that all these threads can be stretched on it horizontally, tied at one end, and weighted with 4 lbs. to each thread at the other. Girls, under the direction of the workwoman who selects the colours, arrange these threads one by one, tying them at one end, weighting them at the other, and supporting them on a steel bar in the middle. This being done, the mass of 17 feet in length is cut up into blocks of 20 inches long each, for convenience in after-operations. All these processes are for one square foot only of the pattern, and they have to be repeated as many times as there are square feet in it. Supposing a rag 6 feet by 2, with a lion, tiger, or other device occupying the greater part of the surface: there must be twelve masses prepared, and as each mass contains 50,000 threads, there will be 600,000 altogether. Blocks are cut from each mass, and are placed in an iron box or frame, side by side; thus forming a quadrangular solid 6 feet by 2, and 20 inches deep, with the threads arranged vertically.

Now, to convert this into a great number of separate rugs, the pattern of which is seen represented on the upper surface, formed by the ends of the coloured threads, india-rubber is dissolved in camphine to the consistence of carpenters' glue, and brushed well over the top, so that every individual thread shall receive its portion; this being dried, a second coating is applied; and afterwards a third. A backing of canvas, or of some kind of strong cloth, is cemented down upon the mass of threads by a glue of the same kind, and is scraped and rubbed until it adheres to every individual fibre. When dry, the mass of threads is raised up three-sixteenths of an inch, by a screw acting upon a movable bottom to the box. A very keen circular cutter, 12 feet in diameter, and rotating 170 times per minute, quickly severs a horizontal slice three-sixteenths of an inch thick, the box of threads being caused by an endless screw to travel onwards to meet the cutter. This slice, when turned up, presents the picture complete, in a beautifully soft nap or pile of woollen threads, supported by a canvas or woollen backing. It is a mere question of hand-work to convert this into a rug, carpet, coverlet, or wrapper of any kind. A second repetition of the same processes converts another slice into a second rug; and so on, until the mass of 20 inches in depth has been cut up into about a hundred slices, each forming one rug. As the blocks of 20 inches were originally cut from a mass of 200 inches, the whole mass produces about a thousand rugs, all exactly the same pattern. It is this power of repetition which makes the process pay; for the great preparatory labour of selecting and arranging (say) 600,000 distinct threads could not otherwise be compensated for.

MOSAYLIMA (Little Moalem), one of the most important rivals of Mohammed, belonged to the clan Dál, a division of the tribe of the Bani Hanifah, of Yamáma in Nedjed. The traditions about his life and age are extremely contradictory and legendary. It appears, however, tolerably certain that he had risen to a certain eminence in his tribe, probably as a religious teacher only at first, before Mohammed assumed his prophetic office. The name he was known by among his friends was Rahmán, the Benignant or Merciful; a term which Mohammed adopted as a designation of God himself. This word, which is Aramaic, was a common divine epithet among the Jews, from whom Mohammed took it, together with a vast bulk of dogmas, and ceremonies, and legends. If, however, M., as is supposed by some, assumed that name in the meaning of Messiah, Saviour, it would prove that he had anticipated Mohammed in the apostleship, which is commonly denied. It was in the ninth year of the Hedjrah that M., at the head of an embassy sent by his tribe, appeared before Mohammed, in order to settle certain points of dispute. The traditions are very contradictory on the circumstance whether or not M. was then already the recognised spiritual leader of his tribe. When they were introduced to Mohammed in the mosque, they greeted him with the orthodox salutation of Moslems—viz., 'Salám alayk' (Peace upon thee), and after a brief parley, recited the confession of faith. Shortly after this event, M. openly professed himself to be a prophet, as well as Mohammed. The latter sent a messenger to him, as soon as he heard of this, to request him to reiterate publicly his profession of Islam. M.'s answer was a request that Mohammed should share his power with him. 'From Mosaylima, the Apostle of God,' he wrote, according to Abufeda, 'to Mohammed, the Apostle of God. Now let the earth be half mine, and half thine.' Mohammed speedily replied: 'From Mohammed, the Apostle of God, to Mosaylima, the liar. The earth is God's: He giveth

the same for inheritance unto such of his servants as He pleases, and the happy issue shall attend those who fear Him.' Yet notwithstanding these testimonies, of probably late date, it seems, on the other hand, perfectly certain that Mohammed made very great concessions to his rival—concessions that point to his having secretly nominated M. his successor, and that he by this means bought M.'s open allegiance during his lifetime. It was not a question of dogmas, though they each had special revelations, but a question of supremacy, which was thus settled amicably. 'Mohammed,' M. said, 'is appointed by God to settle the principal points of faith, and I to supplement them.' He further had a revelation, in accordance with Mohammed's: 'We have sent to every nation its own prophet,' to the effect: 'We have given unto thee [M.] a number of people; keep them to thyself, and advance. But be cautious, and desire not too much; and do not enter into rival fights.'

When Mohammed was at the point of death, he desired to write his will. Whatever he may have wished to ordain, is uncertain; it is well known, at all events, that his friends did not obey his order, and refused to furnish him with writing-materials, very probably because they did not like to be bound by his last injunctions. Sprenger supposes that he wished formally to appoint M. his successor, and that it was just this which his surrounding relations feared. M. then openly declared against Islam, and many parodies of the Koran sprang up in the Nedjed, ascribed to him. In the 11th year of the Hedjrah, it at last came to an open breach between the two rival powers. Abu Bekr, the calif, sent Khalid, 'the Sword of the Faith,' with a number of choice troops, to compel M. to submission. M. awaited the enemy at Rowdah, a village in the Wadi Hanifah. So formidable indeed was M.'s force, that Walid is said to have hesitated for a whole day and night before he undertook an assault unanimously disapproved of by his council. On the second morning, however, he advanced, and in a battle which lasted until the evening, contrived, with fearful losses of his own, to gain the victory. M. fell by the hands of a negro slave, and his head was cut off by the conqueror, and placed at the head of a spear, to convince both friends and foes of his death. Khalid then advanced to the slain prophet's birthplace, in order to slay all its inhabitants. They, however, by a clever stratagem contrived to conclude an honourable peace, but had to embrace Islam. The Mosleyman 'heresy' was thus stamped out, and only a few scattered remnants of the new faith contrived to escape to Hass and Basrah, where they may have laid the foundation of the later Karmathian creed.

It is extremely difficult to come to any clear notion of M.'s real doctrines, as all the accounts that have survived of them come from victorious adversaries—adversaries who have not hesitated to invent the most scandalous stories about him. Thus, a love-adventure between M. and the prophetess Sajáh, the wife of a soothsayer of Yamáma, who is supposed to have stayed three days in his tent, is told with great minuteness, even to the obscene conversation that is supposed to have taken place between them during that time; the fact being that this story, which is still told with much relish by the natives, is without the slightest foundation. From the same source, we learn that M. tried to deceive his followers by conjuring-tricks. It seems, on the contrary, that M. was of much higher moral standing than Mohammed himself. Thus, he is said to have enjoyed the highest chastity even among married people: unless there was hope of begetting children, there should be restriction of

conjugal duty. Even the nickname, 'Little Moslem,' given to him seems to indicate that he, too, preached the unity of God, or Islam, as the fundamental doctrine of faith. How far his religion had a socialist tendency, and offered less show of dignity and outward morality to its followers, or whether it rejected fatalism, contained an idea of incarnation, and invested its preachers and teachers with a semi-mediatorial character, as the latest explorer of the Nedjed, Mr Palgrave, tells us, we have no means of judging. But we must receive these conclusions, probably drawn from the information of the natives, with all the greater caution, as that story of the prophetess Sajâh, whom he reports, after his informants, not only to have been properly married to M., but to have, after his death, become a devout partizan of Islam, and to have entered an 'orthodox alliance,' does not, as we said before, deserve the slightest credence.

MO'SKWA, a river of European Russia, a branch of the Oka, which is itself a branch of the Volga. It is celebrated in history for the great battle, called the battle of Borodino (q. v.), fought on its banks, 7th September 1812, from which Ney (q. v.) obtained his title Prince of Moskwa. The M. rises in a marsh in the government of Smolensk, passes close by the towns of Moshaisk and Svenigrod, passes through the city of Moscow, and joins the Oka near Kolomna, in the government of Moscow. The whole length of its course is about 290 miles. A considerable commerce is carried on by boats on the M., and it is directly connected with the Volga by the *M. Canal*.

MOTAZILITES, or MUTAZALITES, a 'heretical' Mohammedan sect, dating a few generations after Mohammed, of which brief mention has been made under the heading MOHAMMEDAN SECTS. Their name is derived from an Arabic word, denoting 'to separate one's self,' and originally applied to any special sect or union of men; but the M. becoming the most important and dangerous in Islam, they received this denomination by way of eminence. They were also called Moattalites—i. e., those who divest God of His attributes—and Kadarija, i. e., 'those who hold that man has a free will, and deny the strict doctrine of predestination.' The first beginnings of this sect are traced to Mabad, who, in the time of Mohammed himself, already began to question predestination, by pointing out how kings carry on unjust wars, kill men, and steal their goods, and all the while pretend to be merely executing God's decrees. The real founder of the sect, as such, however, is Waail b. Ata. He denied God's 'qualities,' such as knowledge, power, will, life, as leading to, if not directly implying, polytheism. As to predestination itself, this he only allowed to exist with regard to the outward good or evil that befalls man, such as illness or recovery, death or life, but man's actions he held to be entirely in his own hands. God, he said, had given commandments to mankind, and it was not to be supposed that He had, at the same time, preordained that some should disobey these commandments, and that, further, they should be punished for it. Man alone was the agent in his good or evil actions, in his belief or unbelief, obedience or disobedience, and he is rewarded according to his deeds. These doctrines were further developed by his disciple, Abu-l-Hudail, who did not deny so absolutely God's 'qualities,' but modified their meaning in the manner of the Greek philosophers, viz., that every quality was also God's essence. The attributes are thus not without but within Him, and so far from being a multiplicity, they merely designate the various ways of the manifestations of the Godhead. God's will he declared to be a

peculiar kind of knowledge, through which God did what He foresaw to be salutary in the end. Man's freedom of action is only possible in this world. In the next, all will be according to necessary laws immutably preordained. The righteous will enjoy everlasting bliss; and for the wicked, everlasting punishment will be decreed. Another very dangerous doctrine of his system was the assumption that, before the Koran had been revealed, man had already come to the conclusion of right and wrong. By his inner intellect, he held, everybody must and does know—even without the aid of the divinely given commandments—whether the thing he is doing be right or wrong, just or unjust, true or false. He is further supposed to have held, that unless a man be killed by violent means, his life would neither be prolonged nor shortened by 'supernatural' agencies. His belief in the traditions was also by no means an absolute one. There was no special security, he said, in a long, unbroken chain of witnesses, considering that one fallible man among them could corrupt the whole truth.

Many were the branches of these Motazilites. There were, apart from the disciples of Abu-l-Hudail, of whom we have just spoken, the Jobbâians, who adopted Abu Ali Al-Wahhab's (Al-Jobbâ'i's) opinion, to the effect, that the knowledge ascribed to God was not an 'attribute;' nor was his knowing 'necessary;' nor did sin prove anything as to the belief or unbelief of him who committed it, who would anyhow be subjected to eternal punishment if he died in it, &c.—Besides these, there were the disciples of Abu Hashem—the Hashemites, who held that an infidel was not the creation of God, who could not produce evil.—Another branch of the M. were the disciples of Ahmed Ibn Hayet, who held that Christ was the eternal word *incarnate*, and assumed a real body; that there were two gods, or creators, one eternal, viz., the Most High God, and the other not eternal, viz., Christ—not unlike the Socinian and Arian theories on this subject; that there is a successive transmigration of the soul from one body into another, and that the last body will enjoy the reward or suffer the punishments due to each soul; and that God will be seen at the resurrection with the eyes of understanding, not of the body.

Four more divisions of this sect are mentioned, viz., the Jâhedhians, whose master's notion about the Koran was, that it was 'a body that might grow into a man, and sometimes into a beast, or to have, as others put it, two faces—one human, the other that of an animal, according to the different interpretations.' He further taught them, that the damned would become fire, and thus be attracted by hell; also, that the mere belief in God and the Prophet constituted a 'faithful.'—Of rather different tendencies was Al-Mozdar, the founder of the branch of the Mozdarians. He not only held the Koran to be uncreated and eternal, but so far from denying God the power of doing evil, he declared it to be possible for God to be a liar and unjust.—Another branch was formed by the Fasharians, who, while they carried man's free agency rather to excess, yet held that God might doom even an infant to eternal punishment—all the while granting that He would be unjust in so doing.—The last of these Motazilite sectarians we shall mention are the Thamamians, who held, after their master, Thamâma, that sinners would undergo eternal damnation and punishment; that free actions have no producing author; and that, at the resurrection, all infidels, atheists, Jews, Christians, Magians, and heretics should be returned to dust. We cannot, in this place, enlarge upon the different schools

founded by the M., nor upon their subsequent fate. The vast scientific development, however, which their doctrines begot, and which resulted in the encyclopædic labours called 'The Treatises of the Sincere Brethren and True Friends,' are touched upon under **SINCERE BROTHERS** (q. v. in SUPPLEMENT).—See Weil, *Geschichte der Khalifen*; Sale's *Koran*; Steiner, *Mutaziliten*; Dieterici, *Transac-tions of the German Oriental Society*, &c.

MOUNTMELICK, a market-town and seat of poor-law union, in Queen's County, province of Leinster, Ireland. It is situated on the river Owennes, a branch of the Barrow, 47 miles directly west-south-west from Dublin. The pop. in 1861 was 3062. The town has long been a chief seat of the Society of Friends, who established a manufactory of coarse woollen friezes and tweeds, by which many poor children are employed. M. was also the seat of other manufactures, especially a foundry, a machine-factory, and a beet-root sugar factory, the results of which, however, were disappointing.

MOUSA, an island of Shetland, remarkable for an object of antiquity styled Burgh-Mousa, which consists of a round tower of the class known in the north of Scotland as Pictish towers. Burgh-Mousa occupies a knoll close upon the rocky sea-beach, from which materials for its construction had been taken. The whole fabric is composed of flat slabs of clay-slate, which have been easily piled together in a compact mass without the aid of mortar. In exterior figure, the tower is round, inclining inwards about

Burgh-Mousa.

half-way up, and then bulging out near the top. Near the foundation, its circumference is 158 feet, and it measures about 40 feet in height. On the side next the sea, there is a doorway, and that is the only exterior aperture. If there were ever any door-posts, they have disappeared; it is feasilily conjectured, however, that instead of employing a door, the inmates had, on emergencies, built up the opening, for which there is an abundance of loose materials at hand. Entering the doorway, we find the wall sixteen feet thick, and looking upwards, feel as if we were at the bottom of a well, for the circular interior has no flooring, and the top is open to the sky. Opposite the doorway, there is an entrance to a passage and stair, which wind upwards, within the thickness of the wall, to the summit of the building. At different places, there are recesses, or galleries, leading off from the stair,

lighted by apertures to the interior; such dismal holes being all that we find in the way of apartments. It is customary to speak of an outer and inner wall; but the two walls, if we so distinguish them, are so firmly bound together by the stair and otherwise, as to afford a united resistance to assault. Obviously, the structure was used as a retreat in case of attack from foreign enemies, against whom missiles could be showered down from the species of battlement formed by the top of the well-knit walls. According to tradition, the tower of Mousa was occupied by Erland, a Norwegian Jarl, about 1154, when it successfully endured a siege that was undertaken to recover a runaway lady; but how any lady could have found accommodation in such miserable quarters, it is difficult to conjecture. The Society of Scottish Antiquaries deserves thanks for having repaired this fine memorial of a former state of society in Shetland. From its comparatively complete state, Burgh-Mousa is considered a good specimen of the Pictish towers, so called.

MOZDO'K, a town and fortress of South Russia, in the government of Caucasus, on the Terek, about 142 miles north of Tiflis, on the route into Georgia. Pop. 10,895, of very mixed descent, but chiefly Armenians.

MUCH WOOLTON (i. e., *Great Woolton*), a town of Lancashire, England, six miles east-south-east from Liverpool. It has a handsome church, with a tower and small dome, and several other places of worship. The town is rapidly increasing in size on account of the proximity of a branch of the North-Western Railway, which runs within two miles. M. W. has long been noted for a stone obtained from a neighbouring quarry, which gives employment to a considerable number of men. Pop. (1861) 3296. A small distance from M. W. is the village of Little Woolton with a pop. of about 1000.

MU'CKERS, the popular name of an extraordinary sect, which sprung up at Königsberg, in Germany, in 1835. The movement seems to have originated in the dualistic and Gnostic views of John Henry Schönherr (who was born at Memel in 1771, and died at Königsberg in 1826) concerning the origination of the universe by the combination of two spiritual and sensual principles. His followers carried out his system much more completely than himself. The most notable of them were two clergymen, Ebel and Diestel, the former an arch-deacon. By them, sexual connection would seem to have been elevated into an act of worship, and the chief means of the sanctification of the flesh, by which the paradisiac state was to be restored. Ebel and Diestel founded a society, to which women—some of noble birth—attached themselves. Three ladies lived in Ebel's house, who were popularly regarded as his three wives; and Mr Hepworth Dixon, in his work entitled *Spiritual Wives* (1868), tells us that one of them, a young widowed countess, whose beloved husband had fallen on the field of Lützen, and whom he enticed from the seclusion and deep melancholy in which she lived, was described by him as representing to him the principle of Light (*Licht-natur*); another of the ladies represented the principle of Darkness (*Finsteris-natur*);

and the third represented the principle of Union (*Umfassung*). The last was his legal wife, but held the most subordinate place in his extraordinary household. Ere long, public feeling was excited against the M., who were said to be guilty, under forms of piety, of the most odious licentiousness in their meetings. The scandal became great in Königsberg, and a garden there acquired the name of the Seraphs' Grove. The subject was brought before the courts (1839—1842), and the result was that Ebel and Diestel were degraded from their offices, and the latter was further punished by imprisonment. It is alleged, however, by some who have examined the whole evidence produced, that the decisions did not proceed upon a calm judicial inquiry, but were dictated by strong prejudice against the accused, on account of their religious views and peculiar eccentricities; and, in particular, that the evidence gives no support whatever to the charge of licentiousness. Mr Hepworth Dixon has directed attention to the similarity of the Mucker movement with that of the Princeites (see AGAPEMONE) in England, and that of the Bible Communists or Perfectionists (q. v.) in America; all of which took place about the same time, and in connection with revival excitement, although it may almost be regarded as certain that the originators of these movements had not even heard of each other.

MUD-FISH (*Amia*), a very curious genus of fishes, forming the family *Amiidae* of the order *Ganoidei* of Müller, although its position among the *Ganoidei* is determined only by anatomical characters, in which it agrees with sturgeons and the rest of that order, for the scales are not ganoid, and are not osseous plates, but are flexible and rounded, and destitute of enamel. Similar scales, however, are found in fossil genera regarded by Agassiz as ganoid. In habit, the M. resembles osseous fishes rather than ganoids. Except in the absence of teeth on the tongue, the mouth resembles that of a trout. The body is long and flexible, with a bony vertebral column; there are two nasal cirri; the head is flat, covered with a very thin mucous skin, immediately under which the bones appear as sculptured plates. More than ten species are known, natives of the fresh waters of America. The WESTERN M. (*A. calva*) is from a foot and a half to three feet long, bluish-black above, white below. It inhabits the great northern lakes of North America, and is found as far south as Carolina. It feeds chiefly on crawfish and other crustaceans. It is not esteemed as an article of food, although sometimes used by the Indians.

MUHESUR, a town of India, in the territory of Indore (q. v.), on the right bank of the Nerbudda, 280 miles north-east of Bombay. The fort contains many houses within its enclosure, but is in bad repair. There is a new palace, built of gray basalt, and overcharged with sculptures of human beings, and of elephants, tigers, and other animals. There are also numerous and costly Hindu temples, erected by Ahalya Bai, relict of Kunda Rao, son of Maharajah Mulhar Rao. The river, which is here about 2000 feet wide, has a rapid stream of blue water, rushing over a rocky bottom; the banks are 60 or 80 feet high in the dry season. Access to the water is gained by a ghât, or vast flight of stone stairs, which extends below the water at its lowest level. Pop. about 17,000.

MÜLLER, JULIUS, a German theologian, was born at Brieg, on April 10, 1801, and is a brother of Charles Otfried Müller (q. v.), the antiquary. He studied at Breslau and Göttingen, at first devoting himself to law, but afterwards to theology. After

much mental struggle, he adopted religious views opposed to those of the Rationalists. In 1825, he was appointed pastor at Schönbrunn and Rosen, near Strehlen, where he remained seven years. Having acquired a high reputation for theological learning, he was appointed in 1831 second university preacher in Göttingen, and there lectured on practical theology and pedagogics. The spirit in which he laboured there may be seen from his sermons, entitled *Das Christliche Leben, seine Kämpfe und seine Vollendung* (The Christian Life, its Struggles and its Perfection; Breal 1834; 3d ed. 1847). In 1834, he became Extraordinary Professor of Theology in Göttingen, and soon after Ordinary Professor in Marburg, from which he went in 1839 to occupy a similar chair in Halle. The work on which his reputation as a theologian chiefly rests is that on Sin, *Die Christliche Lehre von der Sünde* (Breal 1839; 3d ed., revised and enlarged, 2 vols., 1849), which has been translated into English (2 vols., Edin. 1852—1853). He has since published pamphlets on subjects of temporary interest, particularly in vindication of the cause of Evangelical union against the attacks of the rigid Lutherans; and in 1850, he began, in conjunction with Neander and Nitzsch, a periodical, entitled *Deutsche Zeitschrift für Christliche Wissenschaft und Christliche Leben* (Journal of Christian Science and Christian Life), to which he has since been a very frequent contributor.

MUNKA'OS, a market-town of Hungary, situated on an affluent of the Theiss, 178 miles north-east of Pesth. The inhabitants are mostly artisans, and the chief production is hosiery. There are also alum manufactories, saltpetre-works, and in the vicinity, iron-works and mines of rock-crystal, called Hungarian diamonds. A short distance east from the town is the fortress (founded in 1359) of M., built upon an isolated height, which, although small and insignificant-looking, yet, from its strong walls and advantageous position, has, for the last few centuries, withstood many a siege. Since the beginning of the present century, it has been used as a state-prison. Pop. 7385.

MURGAB, a river of Central Asia, which rises on the northern border of Afghanistan, in the Hindu Kush, immediately to the north of the sources of the Heri (q. v. in SUPPLEMENT). The M. flows westward, then north-westward, and finally northward, passing from amongst the mountains in which it has its source into the desert plains of Turkestan, where the volume of its water gradually diminishes, until it finally loses itself in a swamp in the sandy plain of Merv, after a course of about 400 miles. In the upper part of its course it receives many tributaries, but none in the lower. The most noteworthy place on its banks is Merv, or Meru (anc. *Antiochia Margiana*), a town of Independent Turkestan, about 300 miles south-east from Khiva. Merv was an important town in the days of the Seljuk dynasty, of which it was the capital, but is now very ruinous.

MURO, an episcopal town of South Italy, in the province of Potenza, 17 miles north-west of the town of Potenza. Its castle, built on a height overlooking the ravine, was the scene of the murder of Joanna I., queen of Naples. Pop. (1861) 8260.

MUSCULAR FORCE, ORIGIN OF. During the last two years, the investigations of Professor Fick and Willicenus* of Zürich, of Professor Frankland and of Professor Parkes, have completely

* A translation of their Memoir may be found in the *Philosophical Magazine* for June 1866 (supplementary number).

overthrown the physiological views on this subject held previous to the year 1866. While the inference from previous experiments was, that the effect of exercise was to cause a very large increase in the elimination of carbon, and a much smaller, but very perceptible increase in the elimination of nitrogen, Fick and Wislicenus (from observations made on the excretion of nitrogen during the ascent of the Faulhorn) deny altogether the increase of the nitrogen, and come to the conclusion, that the force generated in the muscles is the result of the burning (oxidation) of non-nitrogenous substances (fats or carbo-hydrates), and not of the burning of the albuminous constituents of muscular tissue; and they conclude, that the nitrogenous constituents of muscles are rather to be regarded as forming the machine in which these fats or carbo-hydrates are burned, than as the subjects which are burned. Dr Frankland (*Philosophical Magazine*, September 1866) arrives at the conclusion that the non-nitrogenous constituents of the food, such as starch, fat, &c., are the chief sources of the actual energy which becomes partially transformed into muscular work. He does not, however, deny to the albuminous matters a co-operation in the production of muscular power, but he regards their chief use as being to renew the muscular tissue. The muscles are thus the source both of animal heat and of muscular force. The latest investigator of this important subject is Professor Parkes, who communicated the result of his inquiries to the Royal Society (see *Proceedings of the Royal Society*, Nos. 89 and 94, 1867). Two series of experiments were made on soldiers at Netley. Two men were kept on ordinary diet and on usual work for four days; were then kept in perfect rest for two days, on a diet free from nitrogen; then finally returned for four days more to their usual food and work. In the second series, the same course was adopted, except that throughout the whole period the men took a constant quantity (302 grains) of nitrogen daily.

The conclusions deduced by Dr Parkes from these experiments were, that Professors Fick and Wislicenus are quite correct in stating that there is no increase of nitrogen eliminated during the period of exercise. There is, on the contrary, a slight decrease. They are not correct in stating that there is no increase after exercise, for there is a perceptible, though not a very large increase. 'Without going into an analysis of the experiments, which would occupy too much space, I believe,' says Dr Parkes in his *Sanitary Report*, contained in the last volume of the *Army Statistical, Sanitary, and Medical Reports*, 1867, p. 346, 'my results indicate that our ideas of the origin of muscular force and of nutrition generally, must be modified; that during action, muscles appropriate nitrogen, and grow; and that they do not give it off and waste, as was formerly supposed, or undergo no change, as Fick and Wislicenus believe. In other words, formation of nitrogenous tissues goes on during action, and removal of nitrogen goes on during rest. The mechanical force manifested during muscular action is, however, probably derived from changes in the carbo-hydrates, especially the fats, which changes are connected with the appropriation of nitrogen by the muscles.'

The theory of muscular action which he proposes for consideration is this. During action, the muscles appropriate nitrogen; this act is accompanied by changes in the carbo-hydrates, which lead to the manifestation of mechanical force; these changes lead to effete products (lactic acid, &c.) in the muscles, which, as appears from Ranke's experiments, stop their contraction. Then ensues an action of oxygen upon the nitrogenous framework

of the muscle, and a removal of the effete products of the carbo-hydrates, so that the muscle becomes again capable of appropriating nitrogen, and of acting. The amount of truth in this theory must be decided by the investigations of others; it seems the only one which can explain the facts, if these have been correctly made out.

Although it is mainly to the above-named physiologists that we owe our recently acquired knowledge, it deserves mention that previous investigations undertaken on different but allied subjects by other physiological chemists, as, for example, Dr Edward Smith, Lawes and Gilbert, Playfair, and Haughton, are entirely in accordance with our new views.

MUSIC RECORDER. Many forms of apparatus have been invented for writing down music in a legible form by the very act of playing it on a keyed instrument, such as the pianoforte or organ. Beginning with 1747, various attempts had been made to effect this object, when, in 1863, Mr Fenby invented and patented his *Phonograph*, in which he brought in the aid of electro-magnetism. His chief aim, as an improvement on previous apparatus, was to devise a method of denoting the length of the notes, as well as their pitch and the interval between them. On pressing down any key of the instrument, a stud on the under side touches a spring; the spring sets in action a small electro-magnetic apparatus, which causes a tracer to pass against a strip of paper moving onward at a uniform rate by means of a cylinder and clockwork. The paper is chemically prepared, so as to receive a brown stain whenever the tracer passes along its surface. The length of each note is expressed by horizontal dashes of greater or less length, made by the tracer; and the arrangement is such as to denote the lines of the stave as well as the character of the note. By subsidiary adjustments, the apparatus is made to express accidental sharps and flats, changes of time, &c.

The Abbé Moigno's *Phonautograph*, introduced to the British Association in 1860, is a contrivance—not for noting down sounds in any kind of musical notation—but for causing a vibrating surface to tell its number and character of vibrations. A kind of spheroidal drum is covered at one end with a diaphragm or stretched membrane; a sheet of paper is carried along this drum-head by means of clockwork; and a system of small levers moves a pen. A tuning-fork, an organ-pipe, or the voice is sounded in proximity to the drum, the body of air within which acts as a reinforcement of the sound; the membrane vibrates in a manner which can be felt by the pen, although not seen by the eye; and the pen makes zigzag markings on the paper. When the sound is produced by a tuning-fork or an organ-pipe, the zigzag lines are so regular that they serve to count the number of vibrations belonging to each particular note. When the sound is that of a singing voice, the markings become very peculiar, especially in such words as contain the gutturals *r, g, &c.*

MUTTRA, a town of British India, capital of the district of the same name, 97 miles south-south-east of Delhi, is situated on the right bank of the Jumna. The fort was built by the celebrated astronomer, Jey Singh (who became Prince of Amber in 1693); and on the roof of one of the apartments is a ruinous observatory, containing a great number of astronomical instruments. Access is had to the river—which, along with the town, is considered sacred by the Hindus—by numerous ghāts, ornamented with little temples; and its banks are, every morning and evening, crowded by devotees of all ages and both sexes, to perform their religious exercises. In Hindu Mythology, it is regarded

as the birthplace of the divinity Krishna. In honour of the monkey-god Hanuman, monkeys are here protected and fed, being allowed to swarm everywhere. There are also great numbers of parrots, peacocks, and sacred bulls at large, without owners. There is a very extensive military cantonment about a mile south of the town. M. appears at an early period to have been of much more importance than it is at present; and its enormous wealth and splendour made it an object of attack to the first Afghan invaders. Mahmud of Ghuznee, in 1017, gave it up to plunder, breaking down and burning all the idols, and amassing a vast quantity

of gold and silver, of which the idols were made. After this calamity, it sank into comparative obscurity. In October 1803, it was, without resistance, occupied by the British troops. Pop. 65,749.

MYNPURI, a town of British India, capital of a district of the same name, is situated on the banks of the small river Eeun, an affluent of the Ganges, 160 miles south-east of Delhi. It lies at an elevation of 620 feet above the sea, and is a favourite station for troops, as provisions and water are abundant and good. M. possesses a Jain temple. The rebels were driven from this place in 1857. Pop. 20,921.

N

N'FTIA, LAGO, a curious small lake in Sicily, about two miles from Mineo, in Catania. It is situated in a plain, amidst craggy hills, and is of a circular form, commonly 60 or 70 yards in diameter, and about 15 feet deep, but in dry weather shrinking to a much smaller size, and being occasionally altogether dried up. In the midst of it are three small craters, two of which perpetually send up water in jets to the height of two or three feet; the third is more intermittent. The water is greenish, or turbid, and has an odour of bitumen. The whole lake resembles a boiling caldron, from the escape of carbonic acid gas, rushing upwards with great force. The atmosphere is consequently fatal to birds attempting to fly across the surface of the lake, and to small animals which approach it to satisfy their thirst; and an approach to it is attended with headache and other painful circumstances to man himself. The ancients regarded these phenomena with great dread. They supposed that Pluto, when carrying off Proserpine, drove his fiery steeds through this lake, ere his descent to the lower regions. A temple was erected here to the gods of the two craters, the *Dii Palici*, who were supposed to be twin sons of Jupiter by the nymph Thalia. Pilgrims flocked to this shrine; and it afforded an inviolable asylum to slaves who had fled from their masters. An oath by the *Dii Palici* was never broken by the master, who found himself compelled here to come to terms with his runaway slave. No remains of the temple of the *Dii Palici* are left, although it is described as having been magnificent.

NAGY KAROLY (i. e., Great Karoly), a town of Hungary, capital of the county Szathmar, 37 miles east-north-east from Debreczin, on a small feeder of the Theiss. It has several important annual fairs, and a trade in corn and cattle. Pop. 10,670.

NAMAYCUSH (*Salmo namaycush*), a fish nearly allied to the salmon and trout, a native of the great lakes and interior rivers of North America. It is often taken of a size varying from 20 to 40 lbs., and is said sometimes to reach 60 lbs. It is much esteemed for the table. It is caught at the same fisheries with the still more prized Whitefish (q. v.).

NANAS, a town of Hungary, in the midst of extensive morasses, about 110 miles east-north-east from Pesth. The population, partly Protestant and

partly Roman Catholic, is employed in cattle-husbandry and agricultural pursuits. Pop. 11,337.

NANA SAHIB, a Hindu, one of the leaders of the sepoy revolt of 1857. He was said to be the son of a Brahman from the Deccan, and his real name was Dhundu Punt. He was born about 1820, and was adopted as a son in 1827 by Bajee Rao, the childless ex-peishwa of Poona, thereby, according to Hindu law and custom, acquiring most of the rights of a legitimate son. He was educated as a Hindu nobleman—taught English, and brought much in contact with the European officers, in whose amusements he seemed fond of participating. A decision was, however, come to by the government of Calcutta, that they should not recognise rights to pensions or indemnities acquired by adoption; and in consequence, N. S. was refused the continuance of a pension of eight lacs of rupees, paid to his adopted father under a treaty made in 1818. This is believed to have rankled in his mind, along with slights he received from the supercilious English youth with whom he came in contact. He was allowed to retain some of the state of a native prince—a retinue of 200 soldiers, with 3 field-pieces, and a fortified residence at Bithoor, 10 miles west of Cawnpore. When the mutiny broke out in May 1857, he offered to assist the English, but instead, he treacherously placed himself at the head of the mutineers. The European troops were induced, on the 25th of June, to capitulate to N. S., who promised they should be sent down the Ganges in safety. They got on board boats provided for them, but had no sooner done so, than two guns were unmasked, and a murderous fire was opened upon them. The sepoys were ordered to shoot the men, but to spare the women and children, who, when their husbands and parents had been shot, were removed to a house in Cawnpore. On the 15th July, Sir H. Havelock, who had advanced to their assistance from Allahabad, defeated the sepoys in two engagements, one within 8 miles of Cawnpore; and N. S. next day directed that the women and children should be put to death, an order carried out with unparalleled atrocity. A long series of engagements against N. S. followed, in which he was always the loser, and he was ultimately driven beyond the English frontier into Nepal. In 1860, his death was announced, but two years later, new movements were discovered, which were attributed to him, and it is not certainly known whether he is dead or alive. Several persons have been arrested on suspicion of being N. S., but in all cases a mistake

has been made. A column has been erected at Cawnpore in memory of those who perished in the massacre.

NAPOLÉON-VENDÉE, or **BOURBON-VENDÉE**, a town of France, the capital of the dep. of Vendée, pleasantly situated on a hill on the right bank of the Yon, 37 miles south from Nantes. The town has no manufactures, and little trade, but derives its importance chiefly from its being the seat of departmental administration. The town contained only 800 inhabitants when Napoleon I. selected it for the capital of the department, granted great sums for its improvement, and gave it its present name, which was changed to *Bourbon-Vendée* at the restoration of the Bourbon family, the name *Napoleon-Vendée* coming again into use on the accession of Napoleon III. Pop. (in 1866) 6791.

NARDO (anc. *Neretum*), a town of South Italy, in the province of Lecce, 8 miles north-north-east from Gallipoli. N. has manufactures of cotton goods and snuff, from cotton and tobacco grown in the neighbourhood. The surrounding country abounds in olive plantations. Pop. (1861) 7513.

NASSI'CK, or **NASHIK**, a town of British India, in the presidency of Bombay, and district of Ahmednugur, 95 miles north-east of Bombay, on the river Godavery, not far from its source. It is a town of great sacredness in the estimation of the Hindus—more revered than even Benares—is a great place of pilgrimage, the chief seat of Brahmanism in the Deccan, and the residence of many families of Brahmans, some of them living in great affluence. It contains many temples, which are built along both banks of the Godavery, and on rocks in the river. They are all of black basalt, and dedicated to Siva. Of far greater interest, however, are the Buddhist caves, about 5 miles from the town, which are situated in a conical hill, at a height of about 100 yards from its base. They are rudely executed. The figures which they contain are in a state of good preservation, and the leading figures are those of Buddha; but the whole character of the remains is thought to indicate Buddhism in a state of transition or compromise with Brahmanism. One cave is 45 feet square, and its flat roof is wholly unsupported. Notwithstanding the Buddhist origin and character of these caves, the Brahmans of N., for the sake of gain, encourage the popular reverence for them. N. contains a resident pop. of about 25,000.

NATIONAL EDUCATION, SYSTEMS OF, the provision made by various states for the education of their citizens. In England, the term national education is commonly used as implying only a provision made for the instruction of children of the poorer classes. But it is capable of a much more extensive application, and in most of the countries in which the state provides for the education of the people, the state regulates, more or less, all instruction, from that of the primary school to that of the university. In England national education has no existence. The Parish Schools (q. v.) of Scotland at one time made a near approach to being national, but the altered religious circumstances of the country have made them cease to be so. The imperfect means adopted to supply the deficiency in both parts of the kingdom, are described under the head of **PRIVY COUNCIL, COMMITTEE OF, ON EDUCATION**. See also **SCHOOLS, PUBLIC AND GRAMMAR; INDUSTRIAL SCHOOLS; REFORMATORY SCHOOLS, &c.** In Ireland the foundation of a really national system was laid in 1833 in the 'National Schools' (supplemented since by the Queen's Colleges and University), the principle of which is briefly stated under **IRELAND**. These

schools have exhibited a steady and even surprising progress, when we consider the determined opposition they have met with from powerful ecclesiastical parties, both Catholic and Protestant. In several of the British colonies the local legislatures have boldly dealt with the question on the national principle, in opposition to the denominational. See **VICTORIA**. As this is likely to be one of the first important subjects to come before the reformed parliament, it may be opportune to give our readers a sketch of what some neighbouring nations have done in regard to it. Before entering upon the description which we propose to give of the principal systems of national education, it will be proper to give some account of the obstacles which have hitherto prevented the establishment of a national system among ourselves, and to indicate some of the matters as to which we have to look for instruction from foreign experience.

And, first, in Great Britain the establishment of a national system of education, and of all interference with education on the part of the state, has until lately been opposed upon principle by a numerous and respectable body of politicians. They for the most part consisted of Dissenters of the middle class, who, beginning with Voluntaryism in ecclesiastical matters, had passed on—at least the leaders had—to the doctrine of *laissez faire* in politics. The others were chiefly speculative persons, deeply imbued with the same doctrine, who, profoundly disbelieving in the wisdom of statesmen, and the capacity of officials, and apparently in the possibility of foresight in large affairs, held that the state should undertake as little as possible, and leave things to what they called their natural course. The arguments used by these two classes were not always alike. Individuals of the former class were apt to go back to the religious ground from which they started, maintaining that education ought to be religious, that the state ought not to teach religion, that therefore education was out of the province of the state. But what the spokesmen of both classes most insisted on was this, that education should be left to the law of supply and demand, or rather, to the voluntary action of individuals, single or combined. It was in that way, they declared, that the education of the people could be most beneficially carried on; for so carried on, it would always be, both in kind and in extent, what, on the whole, the circumstances of the people required. In the hands of government, they said, an educational system must be, more or less, an instrument of state. And at the best, the extent and the quality of the instruction provided must depend upon the will of persons who might be very ignorant of the wants of the people. They used declamation about the bad way in which governments did everything they attempted; about the danger of creating a host of new officials; and about the impropriety of interfering with natural laws, and of discouraging voluntary agency. Then they enlarged upon the great progress which education had made in England since the beginning of this century, independently, as they said, of the state—maintaining not only that it had been as great as the circumstances of the country permitted, but that it was almost as much as the state had accomplished in any country; and that it proved that in England, supply and demand, or the voluntary principle, would soon provide for the education of the whole people. The greater part of the increase in the supply of education, so far as it was not due to the action of the state, had come from the benevolent exertions of individuals. But their chief reliance was upon the agency of individuals or societies inspired by benevolence or

religious zeal. They held that the same objections did not apply to voluntary organisations which lay against the state; they declared that it was the great glory of England to accomplish by such means things which elsewhere were attempted only by the state. Combined voluntary action, they said, was consonant with the national habits and institutions; it was a part of the system which had made the English a free, self-reliant, and enterprising race; it should be fostered, not discouraged; and it was worth our while to pay a price if necessary, rather than let it be superseded by the action of the state.

It was answered, first, that the commercial principle of supply and demand, unless supplemented by the benevolence of individuals, could not be expected to educate the people except by very slow degrees; that education must create the demand for education; that children of the lower classes in large towns, unless assistance or stimulation came to them from without, had at present no more chance of receiving instruction than if they were living in Africa. And the nation would lose incalculably by delay in educating the masses; for nothing would so greatly increase its power and prosperity, so materially improve the condition of the humbler classes, as the education of the whole people. The importance of voluntary agencies was admitted; but why was the state to be precluded from at least co-operating with them? The state, it was said, had a greater interest in educating the people than any of her citizens could have; and, moreover—this was the real question—could undertake it more successfully.

Voluntary agency, it was maintained, was too slow, too uncertain, too spasmodic in operation, to be permanently and solely relied upon in a matter of such great national concern. The friends of state action confidently appealed to the experience of foreign countries as shewing the superior efficiency of state education, and pointed to the effects which government stimulation, on a limited scale, had had at home. It is now several years since this controversy was at its height. The Voluntaries have since that been acquiescing in the interference of the state with education; and recently, several of their foremost men have frankly admitted that they had been mistaken, and that the state, by what it has done for education, has made good its claim to the regulation of it. The course of political events has recently added greatly to the importance of popular education; and at present it may be said that there is practically no opposition upon principle to the control of education by the state.

There have always, however, been obstacles to the establishment of a national system more formidable than the opposition of the Voluntaries, and these appear to remain unabated.

The most important of them are those which are concerned with the place, if any, to be assigned to religion in the school instruction. Upon this matter, there is a conflict of opinions which seems almost irreconcilable. A party, which is growing in numbers, and which is respectable from its activity and intelligence, holds that the state should give nothing but secular instruction; that religion is beyond its province, and should not be taught within its schools; that, indeed, with a population divided into numerous sects, a practicable scheme of state education embracing religion cannot be devised. To this party, a portion of the English Voluntaries now seems disposed to ally itself. There are others who believe it possible to teach an undenominational Christianity in schools; who desire that the state schoolmaster should confine himself to this; and that dogmatic teaching should be left to the religious bodies. A third party hold that dogmatic

teaching should be given in state schools; that religious teaching, to have any value, must be dogmatic; but that arrangements might be made for the religious instruction of children by persons of their own persuasions; and, at any rate, that children should be exempted from the religious instruction given in a school, if their parents should so desire. The most numerous body of all are satisfied with the system of aiding denominational schools which now exists; because they approve of schools being, as for the most part they now are, under clerical supervision, and fear that by any change the influence of the clergy upon education would be weakened. Among the managers of Church of England schools, fault is scarcely found with more than one point in the present system; there is an incessant agitation against the 'Conscience Clause,' which the state has placed among the conditions of its aid, by which is stipulated that religious instruction shall not be given contrary to the wish of the parent. Between the Denominationalist and the Secularist there is a difference which scarcely admits of compromise; and until they agree, a national system is hardly possible. The former would most probably oppose any scheme for supplementing the Denominational system—for the purpose of educating the classes which this system does not educate—unless it were to include religious teaching.

The question of religious instruction has been found a troublesome one in nearly every country where the state regulates education, and there is nothing more instructive, in foreign experience, than the ways in which, in different systems, this difficulty has been disposed of. Next to this, the most important thing to be observed is, the parts which, in different systems, are assigned to the state and to the locality respectively; for it is unquestionable that there are some dangers attaching to state education, when the influence of the state is predominant, and that the function of the state in education must be carefully defined. By the mere selection of school-books, the state could powerfully influence the rising generation; and in Austria, and, it is said, in France also, the school has been made use of as an instrument of state policy. With a popular government, however, there is not much risk of it being used for sinister purposes; and in this country, we are in more danger of having recourse too little to the powers of the state than of trusting it too much. The possibility of making education compulsory, is another matter upon which foreign systems of education throw much light; we are perhaps more interested in noting how far indirect methods can be resorted to for compelling attendance at the schools. Upon the limits of the instruction which should be attempted in schools for the poorer classes—a subject which has been much discussed in connection with the Revised Code of 1861—and upon the results of government regulation of the middle and upper schools also, there is much to be learned from the foreign educational systems. We begin with

State-education in Holland.

There are several countries in which—if school statistics could be taken as a test—popular instruction is more widely diffused than it is in Holland; but in no European country is it so uncommon to meet a man who cannot easily read and write. The primary schools of Holland have a high reputation for the solidity of the instruction they impart, and have, by competent observers, been declared to be the best in Europe. A small and wealthy state—rich, too, in the public spirit of its citizens—with a population singularly docile and orderly, the task of educating the people has been

for Holland exceptionally free from difficulty. It had the start of most other European nations in the work of popular education. So far back as 1811, its primary schools had been celebrated in a Report by the famous Cuvier. It has had an education law since 1806; and of this law, though it underwent modification in 1857, it is necessary to give some account. Its author was M. Van Den Ende, who, from 1806 till 1833, had the superintendance of popular education in the country.

On the face of it, this law seemed far from making a complete provision for the education of the people; it left much—in any other country, it would have been a great deal too much—to the public spirit of local authorities. It did not make education compulsory; it did not even enforce the establishment of public schools; but it provided for two things being done thoroughly—the inspection of the schools and the examination of the teachers—and to this seems to have been chiefly due its eminent success. Each province of Holland was formed into a certain number of school-districts, and over each school-district was placed an inspector. The inspector was made supreme over primary instruction in his district. He was a member of every school-committee, and school-committees could be named only with his concurrence; no teacher, public or private, could exercise his calling without his permission; and he inspected every school in his district twice a year. The united inspectors of the province formed the provincial commission for primary education. This commission met three times a year, and received from each of its members a report upon his district; once a year, it sent a deputy to the Hague, to form, with the deputies from other provinces, a commission to discuss and regulate school-matters, under the direction of the Minister for the Home Department and his Inspector-general. The inspectors in the various provinces were appointed by the Home Office, on the presentation of the provincial commission. It has been said that in Holland public spirit is very strong. State-employments are thus deemed very honourable; and the inspectors gave their services gratuitously—receiving only an allowance for expenses. It was one of the duties of the provincial commission to examine teachers for certificates. First, the teacher had to get a *general admission*—a certificate of competency, admitting him into the teaching profession; he had to get a *special admission* also, before he could exercise his profession. There were four grades of certificates—the first or second grade had to be obtained by a school-master, public or private, in the towns; the third grade qualified for a village-school; the fourth grade was for under-masters and assistants. To the highest grade were admitted those candidates only who gave signs of a *distinguished culture*. For public masterships, when they fell vacant, a competitive examination was held; the successful candidate received his *special admission*—his appointment to exercise his profession in the school. For special admission as a private teacher, there was no second examination; it was in the power of the municipality, with the concurrence of the inspector, to grant it upon application. Although there were no obligatory provisions in the law, the provincial and communal administrations were charged by the government to provide the means of instruction in their localities, to insure a comfortable subsistence for teachers, and to obtain a regular attendance of the children in the schools; and they did all this to the best of their ability. Free schools for the poor were provided in the towns; in the villages, schools to which the poor were admitted gratuitously. Every effort was used, both by the lay

authorities and the clergy, to draw poor children into the schools; and the schoolmasters were provided with incomes much superior to what is usually paid to schoolmasters in any other European country. To this M. Cuvier attributed much of the success of the Dutch schools. Some of the best scholars were kept in the school to assist in the teaching; they became under-masters, and eventually masters; and thus, even before the institution of normal schools, an efficient body of teachers was provided. In the normal schools which were afterwards established, school-methods and the practice of teaching formed a more prominent part of the instruction than in those of other countries. It soon appeared, that the free schools for the poor in towns were giving better instruction than could be obtained by the lower middling classes; and intermediate schools had to be established in the towns (*tuaschen-schoolen*), in which, for a small fee, an excellent education was provided. Above the intermediate school was the French school, in which, besides a sound commercial education, modern languages were taught; above that was the Latin school, giving a classical education, and preparing for the universities. The classical schools and the universities of Holland do not receive from foreign observers the commendation so freely bestowed upon the other parts of the educational system of the country.

Under this law, the public schools were non-denominational; no dogmatic instruction was to be given by the teacher or in the school; but the instruction was to be such as to 'train its recipients for the exercise of all social and Christian virtues.' The religious education of the children, however, was not overlooked. The government exhorted the clergy of the different communions to take upon them the religious instruction of children of their own persuasions; and this the clergy willingly did—giving up a portion of every Sunday to this duty. The schoolmaster instructed the children in the truths common to all religions, and on Saturdays, when the Jews were absent, in the New Testament and the Life of Christ. M. Cuvier, in 1811, stated that he found the education religious, though not dogmatic; and in 1836, high satisfaction with it was expressed by M. Cousin, an earnest advocate of religious education. It was thought that the Dutch schools had proved the possibility of teaching in schools an unsectarian Christianity. But it was chiefly upon this point that the controversy arose which led to the enactment of 1857; and as regards it, it cannot be said that the controversy is yet ended.

There were other matters which excited a demand for the alterations then made in the law. The constitution of 1848 had granted the liberty of instruction, and was therefore in conflict with the law of 1806. The school-attendance had been falling off. Some of the municipalities had been evading their duty to the schoolmasters and the schools. It was thought desirable that the duties of the commune in regard to education should be carefully defined by law. The changes made, however, were not of much practical importance.

The law of 1857 granted 'liberty of instruction;' still requiring from the private teacher the certificate of competency, it rid him of the veto of the municipality and the inspector. It expressly prescribes that primary schools, in each commune, shall be at the commune's charge; they are to be in sufficient number; and the states' deputies and the supreme government are to judge whether, in any commune, they are in sufficient number or not. If the charge of its schools is too heavy for a

commune, it receives a grant in aid, of which the state and the province each contributes half; but there is no fixed point at which the commune can demand this aid. The law fixes the minimum salary for a schoolmaster at 400 florins (about £34); for an under-master at 200 florins. (The schoolmaster's salary, however, is usually much higher; in towns, not unfrequently four times as much.) It provides that when the number of scholars exceeds 70, the master is to have the aid of a pupil-teacher; when it exceeds 100, of an under-master; when it exceeds 150, of an under-master and pupil-teacher; for every 50 scholars above this last number, he is allowed another pupil-teacher; for every 100 scholars, another under-master. School-fees are to be exacted only of those who can afford to pay them; and the municipalities are enjoined to 'provide as far as possible for the attendance at school of all children whose parents are in the receipt of public relief.' The law defines the subjects of primary instruction as follows: Reading, writing, arithmetic, the elements of geometry, of Dutch grammar, of geography, of history, of the natural sciences, and singing. There is still a competitive examination for the office of public schoolmaster; a list of those who have acquitted themselves best is made up by the inspector and a committee of the communal council, and from this list the selection is made by the whole body of the council. For the provincial commission, consisting of the inspectors of the province, there has been substituted a salaried provincial inspector; and the provincial inspectors are assembled once a year to deliberate upon the state of primary instruction. The Minister of the Home Department, assisted by a referendary, is the supreme authority in matters connected with education.

Upon the subject of religious instruction, the law was left unaltered. The enactment of 1857 provides as follows: 'Primary instruction, while it imparts the information necessary, is to tend to develop the reason of the young, and to train them to the exercise of all Christian and social virtues. The teacher shall abstain from teaching, doing, or permitting anything contrary to the respect due to the convictions of Dissenters. Religious instruction is left to the different religious communions. The schoolroom may be put at their disposal for that purpose, for the benefit of children attending school, out of school-hours.' This was the conclusion arrived at, after much excited discussion.

In 1848, all religions were, in Holland, placed by the law on a perfect equality; and immediately thereafter, an attack was begun by the Roman Catholics on the religious instruction of the schools. Professedly neutral, they maintained that it was really Protestant, and probably they were right. The schoolmasters, on the demand of the Roman Catholics, were enjoined to comply more strictly with the law; and thereupon there began among the orthodox Protestant bodies a violent agitation against the law—a movement for connecting every public school with some religious communion. The Roman Catholics, believing that in Holland neutral schools must be Protestant, desired that the instruction should be purely secular; and a considerable party among the Protestants contended for the same object. The only party in favour of the existing law were the Rationalist or New-school Protestants, who attach more importance to the moral and civilising side of Christianity than to its dogmatic aspects. Between the Denominationalists on one hand and the Secularists on the other, the victory fell to this last party. Of course, the decision was a compromise; and neither the High Protestant party nor the Roman Catholics regard it with

satisfaction. The consequence has been that, advantage being taken of the newly-conceded freedom of instruction, there has been a great increase in the number of private elementary schools conducted on the denominational basis. The non-denominational school in Holland cannot be considered entirely successful, since the opposition to it seems to be leading to primary education being to a considerable extent taken out of the control of the state.

State-education in Switzerland.

In no part of Europe has the education of the people been more successfully prosecuted than in Switzerland. In all the cantons, French and German, it has been carefully attended to by the governing bodies; and for small communities, provided the rulers have intelligence and public spirit, it is comparatively a simple and easy task. To those who are interested in school-methods and school-management, nothing can be more instructive than the education of the German cantons. Their primary schools are unsurpassed; those of the canton Aargau have the reputation of being the best in Europe. The experience of the French cantons throws light upon more than one of the questions which occur in the construction of a national system. It is with the latter class of questions that we are concerned; and to the French cantons—Geneva, Vaud, Freiburg, Neuchâtel, and the Valais—the following statement is confined.

In these five cantons, the school-system was, until recently, the same in its main outlines; it was a system designed to put public education in harmony with the democratic constitutions established after the war of the Sonderbund. In Vaud, it was founded in 1846; in Geneva and Freiburg, in 1848; in the Valais, in 1849; and in Neuchâtel, in 1850. In Freiburg, it underwent modification in 1856. Its main features were as follows: The communes were required to provide and maintain public schools, the state assisting them when the charge became too heavy. In general, every place with more than 20 children of school-age was required to have its school; every place with more than 50 or 60, a second school; and so on. Infant-schools were recommended and aided by the state, but their establishment was not made obligatory. The council of state—the supreme executive—of the canton appointed a Board of Public Instruction to exercise the government of education; but in important matters, an appeal lay from this body to the council; and by the council only could a master be dismissed. The municipality appointed a communal school-committee, which had the local superintendence of the schools. Ministers of religion were eligible for this body, but were not members of it by virtue of office. It was the duty of the school-committee to visit the schools of its commune not less than once a fortnight, besides holding a public general examination of them once a year. The teacher required to get a certificate of capacity; the examinations for the certificate being under the management of the Board of Public Instruction. In Vaud, however, five years' service in a public school exempted a teacher from the obligation of a certificate; and in other cantons, it does not seem to have been rigidly insisted on. For vacant masterships, there was a competitive examination, to which persons qualified by certificate or service only were properly admitted; in Vaud, however, failing qualified persons, other candidates might be admitted to examination, and provisionally appointed. In Geneva, Freiburg, and the Valais, there were school inspectors who periodically reported to the Board of Public Instruction;

Vaud and Neuchâtel had no inspectors; the duty of inspection in these cantons devolved upon the school-committee. The subjects taught were religion, reading, writing, grammar, arithmetic and book-keeping, geography, Swiss history, and singing. The instruction given had two or more degrees (in Geneva, six degrees), according as these subjects were taught with more or less extension; instruction in both degrees being usually given in the same school, and by the same master. Education was to be based upon the 'principles of Christianity and democracy.' Hours were to be set apart for religious instruction; from the ordinary school-lessons, dogma was to be strictly excluded; and it was regarded as the province of the minister of religion, not of the schoolmaster, to give religious instruction, though the latter was not prevented from giving it in the room of, and under the responsibility of a minister. In all the cantons, except Geneva, education was made compulsory; attendance at school was required from the seventh to the fifteenth, or from the eighth to the sixteenth year. If children were privately educated, the state must be satisfied that their education was sufficient; such children could be called up for examination with the scholars of the public schools, and if found inferior, might be transferred to a public school. A certificate of emancipation was granted when the obligatory course had been fulfilled. The law contemplated that the instruction should be gratuitous, and in Geneva and the Valais it was gratuitous.

In Freiburg, the school-system was framed in no small degree for the purpose of strengthening the democratic party against the clerical party. It provided that no religious society should be allowed to teach; that persons educated by the Jesuits should be incapable of holding any office in church or state; it imposed a political oath upon the schoolmaster; it prohibited children from being sent to a private school, except with the sanction of the inspector and the school-committee; and if sent, required that they should come up for examination every half-year. At the same time, it established an excellent programme of primary instruction. At the elections of 1856, the clerical party regained the ascendancy in Freiburg; and in January 1858, the council of state made a considerable alteration in the school-law. It reduced the programme of primary instruction; it made the clergyman a necessary member of the local school-committee, freed the teacher from the necessity of taking an oath, and relaxed the obligation of attendance at the public schools, giving parents liberty to educate their children at home or at private schools. In other respects, the system, as above described, has been maintained in Freiburg. There has been no change in the other cantons.

The law as regards religious instruction seems to work with tolerable smoothness. In Vaud, it appears that the laxity which prevails as to the requirement of a certificate sometimes leads to the admission of unqualified persons as teachers; and in Vaud and Neuchâtel, complaint is made of the incapacity of the school-committee to make up for the want of professional inspection.

In the four cantons in which education is by law compulsory, the school-attendance is found to be no better than in Geneva, where it is not compulsory. In these cantons, the law provides that parents not sending their children to school are to be warned; if the warning be neglected, that they are to be summoned before the tribunals, which can punish them by fine or imprisonment. But it appears that, in point of fact, the tribunals are never resorted to; and that the authorities are careful not to insist upon more than the people are easily able and willing

to comply with. In the Valais, the school-year need not last for more than five months. In Freiburg, the vacation may last for three months; and the inspector may exempt from attendance at school children who are sufficiently advanced, and children whose labour their parents cannot do without. In Vaud, the local school-committee may grant to children above twelve years of age, whose labour is necessary to their parents, dispensations which in a great measure exempt them from attendance at school; the master may grant the scholar leave of absence for two days in the week; the president of the school-committee may grant him leave for a week at a time; the school-committee itself for a month at a time. It appears that in Vaud, the attendance at the schools had been steadily falling off from 1848, the date of the law, up to 1856; and the attendance of the children whose names were on the books was then reported to be by no means regular. New branches of industry which gave employment to children had been introduced into the canton; and the Council of Public Instruction seems to have been compelled to sacrifice the law to the interests of families. The experiment of compulsory education cannot be said to have succeeded, because it has not really been made, in French Switzerland.

State-education in France.

At the head of the education of France is the Minister of Public Instruction; he is advised and assisted by the Imperial Council of Public Instruction, a body the members of which are appointed by the crown for the period of a year. The minister, if he thinks fit, brings before the council for discussion projected laws and decrees on public education; he is bound to consult it respecting the programmes of study, methods, and books to be adopted in all classes of public schools. The minister has succeeded to the functions in respect of education which, under the first Empire, were conferred upon the University of France; he is head of the university, the officials of which still perform a considerable part in the management of education, but do so under his control. As respects the higher and the professional education, the university is both a teaching and an examining body, granting degrees under conditions prescribed by the minister and council. The administration of the secondary instruction is committed to it, and it shares in the supervision of the primary instruction. It is composed of 18 Academies, each of which comprehends several departments. These academies are so many local centres of the Department of Public Instruction. At the head of each is a rector; the chief officials under him are called Academy inspectors. The Minister of Public Instruction is also rector of the Academy of Paris.

The Academy officials, under the control of the minister, have the superintendence of secondary instruction in the departments within the Academy's jurisdiction; there is an inspector for each department. The instruction is minutely regulated, as to the quantity to be provided, as to the subjects to be comprehended in it, and as to its cost; it is the chief duty of the Academy inspectors to see that the requirements with respect to it are complied with. The inspection is said to be highly efficient. The lyceum is the principal seminary of secondary instruction; in general, the chief town of every French department has its lyceum. There is, besides, the communal college. Every town of considerable population has its communal college. The lyceum is founded and maintained by the state, with aid from the department and the communes; the communal college is founded and

maintained by the commune, with occasional aid from the state. The instruction given in the communal college and in the lyceum is substantially the same in character; in the lyceum it is the more extensive. To the lyceum there is usually attached a preparatory school for the younger boys. In both lycæums and communal colleges, there are boarders and day-scholars. French, Latin, Greek, and mathematics are the principal subjects of instruction; arithmetic, history, geography, modern languages, and the natural sciences are also taught. The course at the lyceum lasts for six years, and qualifies for the degree of Bachelor of Letters. Religious instruction is given—to the Roman Catholic boys, by chaplains attached to the school; to the Protestants, by a Protestant minister specially appointed to this duty; and the New Testament in Greek or Latin is read daily by every class. In the lycæums, the average charge for day-scholars is from 110 francs (£4, 7s. 4d.) to 180 francs (£7, 8s. 4d.) a year; the charge for boarders from 800 francs (£32) to 900 francs (£36), according to their age and advancement. In Paris, the charges are higher—from £38 to £60 a year for boarders, and from £6 to £12 a year for day-scholars; on the other hand, there are lycæums where the highest charge for boarders is £22 a year. There are public scholarships (*bourses*) founded by the state, to be obtained by competition, the holders of which are relieved from all cost. The education given is in no respect much inferior—and in some respects it is superior—to that which is to be had at an enormous cost at the best English public schools; it is far superior to that which, at a far higher cost, is ordinarily given to children of the middle classes in England. A private secondary school cannot be opened without notice to the public authorities: they must be satisfied that the premises are suitable; and the director must have a certificate of probation—showing that he has served five years in a secondary school—and a certificate of competency obtained at the public examination for secondary teachers. The Academy inspector inspects private secondary schools, but only to see that the pupils are properly lodged and fed, and that the teaching contains nothing contrary to morality and the laws. The minister may, however, dispense with the certificate of probation, and holy orders are accepted in lieu of the certificate of competency.

A law, dated the 21st June 1866, founded a new course of study in secondary schools—a special secondary instruction. The object of the special secondary instruction is declared to be to 'found the sub-officers of industry;' instruction in living languages is substituted for the classical instruction of the secondary schools; the elements of science and its applications receive great attention—particular regard being had to the teaching of agriculture and the sciences which bear upon it. The teaching, moreover, is intended to impart what may be called a sound French education. A normal school has been founded at Cluny for the preparation of masters for this special secondary instruction.

For primary instruction in France, an excellent basis was laid by M. Guizot's law of 1833, of which, indeed, the more important provisions have been retained. The body of legislation actually in force consists of the law of March 15, 1850, the organic decree of March 9, 1852, the law of June 14, 1854, and the law passed during the year 1867. The law requires that every commune shall maintain an elementary school, either by itself, or in combination with other communes; in founding and maintaining its schools, it is to be aided, if necessary, by the department and by the state. It must have taxed itself specially for the schools three centimes

per franc of rental before it can claim aid; the department must have taxed itself specially two centimes for the communal schools before the state is resorted to. Up to the present year, a certain number of poor children—the number determined for each school by the prefect of the department—were admitted to the school gratuitously; for others, a fee was charged, which was collected every month by the tax-gatherer. The state contributed whatever was necessary in addition to the communal and departmental taxation and the school-fees. The law of the present year, however, provides that all children are to be admitted gratuitously whose parents would have difficulty in paying the school-fee; and that a commune whose taxation amounts to four centimes additional may dispense with the school-fee altogether, the deficiency, if any, so arising being made up by the state. In the large towns, the schools have long been gratuitous—the communes often taxing themselves, for school-purposes, beyond the amount required by law. Up to the year 1867, the law did not oblige the communes to maintain separate schools for girls, though a large proportion of them contributed towards the maintenance of such schools. The law of 1867 provides for the establishment of girls' schools; the cost of them—the communal and departmental taxation being in most places previously exhausted—will fall in a great measure upon the state.

Religious instruction is given in every school. In France, the Roman Catholic, the Protestant, and the Jewish forms of worship are subsidised by the state; and it is provided that, in communes where more than one of these is publicly professed, each form is to have its separate school. The departmental council, however, has power to authorise the union, in a common school, of children belonging to different communions. For such cases, it is provided that ministers of each communion shall have free and equal access to the school, at separate times, to attend to the religious instruction of members of their own flock. To a school appropriated to one denomination, no child belonging to another is admitted, except at the express demand of his parent or guardian, signified in writing to the teacher. Denominational schools are now the rule, common schools the exception. Previously to 1850, under M. Guizot's law, common schools were the rule, but it was found that in them the religious instruction presented grave practical difficulties. All the religious bodies appear to be satisfied with the present system. The schools, though denominational, are communal schools; the denominations have not the management of them; and they are all subject to the same inspection.

The mayor and the minister of religion in each commune have the supervision and moral direction of the primary school; in practice, they are strictly confined to matters connected with its morality. Cantonal delegates are appointed by the departmental council (the canton is a division larger than the commune), who inspect the primary schools of their canton; but they have no real authority over the schools; they are only allowed to make representations as to the state of the schools to the departmental council, or to the inspector. The departmental council has the chief part in the regulation of the primary schools; moreover, no private primary school can be opened without its permission; and if it refuse permission, there is no appeal. It is the prefect, however, who has the power of nominating, suspending, and dismissing public primary teachers. His authority is usually exercised upon the report of the Academy inspector—the university official whose important functions, in respect of secondary instruction, have already

been described. The academies have the charge of the normal schools of primary instruction, and the supervision of the primary schools as regards the methods of teaching and course of study. Under them are the primary inspectors, who report to the Academy inspectors; above the latter, as regards primary instruction, there are four inspector-generals, attached to the office of education at Paris. It is the primary inspector who really superintends the instruction of the schools; his labours are unceasing, his inspection is a reality, for he is not required to give notice of his visits. The private primary schools are subject to his inspection, but only as regards the provision made for the bodily health and comfort of the pupils and the maintenance of morality.

The subjects which must be taught in every primary school, in addition to moral and religious teaching, are reading, writing, arithmetic, the elements of French grammar, and the French system of weights and measures; there are other subjects which are facultative—which, in whole or in part, may be taught, that is, if the council of the commune should so desire, and the departmental council give its consent. These facultative matters are the applications of arithmetic; the elements of history and of geography; the elements of physics and of natural history; elementary instruction in agriculture, the arts, and hygiene; surveying, levelling, drawing, singing, and gymnastics. For girls, there are superior primary schools which teach the facultative matters only; and in girls' schools, instruction is usually given in needle-work for about three hours a day.

For the preparation of male teachers, the law requires every department to maintain a normal school; in some cases, however, two departments are allowed to maintain one jointly: there are now 70 of these schools. There are separate normal schools for female teachers; of these, the number was recently 34; now that the law is about to add largely to the number of girls' schools, it will probably be increased. The members of the religious orders devoted to teaching, which perform a great part in primary education, are trained for their duties in the establishments of their respective orders. (Of these orders, the most important is that of the Brethren of the Christian Schools.) The instruction of the normal schools is meagre; it scarcely exceeds the subjects of primary instruction; a considerable proportion of the students, indeed, acquire only an imperfect knowledge of the facultative subjects. School-method is what, in the normal schools, it is deemed most important to teach. The examination for primary schoolmasters—which is conducted by a commission appointed by the departmental council—is limited to the subjects taught in the schools. There are two classes of certificates, according as the teacher passes in the obligatory subjects only, or in the whole or part of the facultative subjects also. Every male teacher, public or private, is required to have the certificate of capacity granted after an examination; also, excepting in the case of religious persons, a certificate of morality. The law recognises a certificate of stage, to be granted to assistants who have served as such for three years, as a substitute for the certificate of capacity; but this provision has been unpopular, and the qualification of stage is practically unknown. Female lay teachers require the certificate of capacity; female teachers of the religious orders are exempted from it. No person can be appointed a regular communal teacher unless he be twenty-four years old, and have served for three years since his twenty-first year as an assistant, or as a *supplying* teacher. The supplying teacher gets

a lower salary, and may be employed in the poorer communes. The salaries are low even in the towns: in many of the country communes, the legal minima are not exceeded: these are—for an ordinary communal teacher, £24 a year; for a female teacher, or a supplying teacher, £20 a year. The commune pays £8 a year, besides the school-fees; whatever is required to make up the legal minimum, the government supplies; and, since 1862, the government has, upon certain conditions, made slight allowances in addition to the minimum.

It is in secondary instruction that the education of France has a decided superiority over that of England. The primary instruction is scarcely equal to that given in English schools of the same grade. Mr Matthew Arnold has reported that, in 1859, he found in French primary schools the writing fair, but scarcely so good as in English schools; the reading better, the arithmetic much better, than in English schools. Of history and geography, the pupils were far more ignorant than English school-children of the same age. The ministry of M. Duruy, however, has been an era of improvement; much more attention is given to the facultative matters now; especial attention to agriculture and the subjects connected with the daily life of the peasant. Mr Arnold came to the conclusion, that even in the great towns there were no masses of children left altogether uneducated, that almost all passed at some time through the schools. Adult classes, taught in the evenings, have greatly increased in numbers of late years, and are now aided by the state.

In 1834—just after the passing of M. Guizot's law—the number of primary schools, public and private, was 10,316; in 1857, it was 65,100; in 1865, it was 71,699, of which 42,139 were boys' or mixed schools, 29,560 girls' schools. In addition to this, there were, in 1865, infant schools to the number of 3572, which were more or less aided by the state. In the primary and infant schools, there were, in 1865, 4,850,000 scholars—3,500,000 more than the number of scholars in 1829. Upwards of 2,000,000 children were admitted to the schools gratuitously. It is estimated that the law of the present year will lead to the establishment of 11,000 new schools, of which 8000 will be for girls; and it was stated in the debate in the Corps Législatif, in March 1867, that it would probably increase the cost of education to the state by seven or eight million francs. In the budget of 1866 the cost to the state of the ordinary service of public instruction was put at 19,918,121 francs (£796,725); the secondary instruction costing 3,141,000 francs (£125,640); and the primary instruction 6,863,100 francs (£274,524). There was also, on account of primary instruction, an extraordinary expense of 1,100,000 francs (£44,000).

State-education in Prussia.

In all the Protestant states of Germany, the school-system in its main features is the same. The Prussian system—more celebrated, more extensive, more practical and thorough than the system of the minor states—always powerfully influencing these, and now likely to influence them more than ever, is that which must be selected for description. About this system, M. Cousin, by a strange confusion between it and a project of law—a mere scheme drawn up by the education minister, Von Altenstein, never even proposed for legislation—spread misconceptions throughout Europe, which have scarcely yet been dispelled. It has been greatly changed, greatly improved since Cousin wrote in 1831; but it does not yet in symmetry and completeness approach to what he described.

In Prussia, there is a Minister of Public Worship and Instruction; but the officials who under him carry on the government of education are the officials of the Department of the Interior. At the head of the government in each province is a president; over each of the departments into which the province is divided there is a prefect (*bezirk*); each of these officers is assisted by a council, of which one section, called *Schulcollegium*, forms a separate council for deliberating upon the local school-affairs. One member of the school-council, called provincial school-councillor, is associated with the president for administrative purposes: the prefect has attached to him two departmental school-councillors, one Protestant, one Catholic, to advise with him, and to administer the school-affairs of their respective communitons. There is practically a division made of educational affairs between the officials of the province and those of the department. The provincial school-councillor takes the charge of secondary education within the province; the departmental school-councillors the charge of the primary schools of the department.

Over each of the circles into which the department is divided is an officer, termed a *Landrath*, who reports to the prefect of the department. With the *landrath*, in the management of primary schools, is associated the *superintendent*, the church dignitary of the circle. The superintendent is *ex-officio* inspector of the primary schools within the district. The parish clergyman is *ex-officio* local inspector of primary schools within his parish. There is also for the school or schools of each parish a board of managers, the composition of which varies in different provinces. The clergyman is always a member of it: he is usually chairman. In country places, the whole powers of the board are often left in his hands.

In the 'exterior' affairs of the school—passing school-accounts, visitation of school-premises, control of the school-estates, adjustment of the school-rate, &c.—the *landrath* is associated with the superintendent. Its 'interior' affairs, all that concerns its teaching and discipline, are, subject to the established regulations, under the superintendent's control; but, in practice, they are more under the influence of the departmental school-councillor. The superintendent, however, is required to visit the schools, and to watch over the conduct of the local inspector, and he reports annually to the government of the department. The local inspector's province is the interior affairs of the school. He is expected to visit the schools diligently, and to be active in the supervision of them. The religious teaching of the children is almost entirely done by him, it being his duty to prepare them for confirmation, which comes at the end of the school-period. To qualify them for the duty of school-inspection, the candidates of theology are required to attend for six weeks as auditors at a normal school, and to have attended a course of *Pädagogik* at the university. Nevertheless, it appears that many clergymen are very ill fitted for this work, and that their powers of interference are often exercised in ways annoying to the master, and detrimental to the school. The 'exterior' affairs of the schools of a parish belong to the board of managers.

This board is usually composed of representatives (1) of the patrons, if any, of the school; (2) of the parochial clergy; (3) of the municipal body; (4) of the householders. It has a stated meeting once a quarter; it meets whenever it is summoned by the chairman. It manages the revenue and expenditure of the school, in respect of which it is responsible to the *landrath*; it is the trustee of the school-

buildings and property. It is its duty to see that the regular school-hours are kept; that no unauthorised holidays are given; to it application must be made for dispensations for periods exceeding a week. Its members should be present at all examinations and other public solemnities of the school. In the large towns, there are school-delegacies appointed by the *Magistrat*, whose powers are more extensive, and are in practice the greater, because in the large towns the pastors pay little attention to the schools. The school-delegacies have control over the higher as well as the primary schools which their constituents maintain; two paid members—school-delegates—who must be members of the *Magistrat*, exercise the greater part of their authority. Under the delegacy, for every school there is a school-board, consisting of the clergyman and two lay members, whom the delegacy appoints. The delegacy itself is accountable to the magistrat, and both are subordinate to the provincial council.

Every commune is bound to find school-room and teachers for all the children of school-age belonging to it. The amount of the teacher's stipend is in every case fixed by the departmental government; there is no legal minimum; the salaries are usually very low. Some parishes possess endowments; but, in general, the cost of maintaining the schools is defrayed by means of (1) school-fees, (2) a local rate, (3) a grant from the national treasury. As children are only expected to pay what they can, and as the state grants aid only after the strictest proof of the incapacity of the commune, the weight of the burden falls upon the local rate. The maintenance of the schools ranks with the first charges upon the local purse. The teacher is appointed by the departmental councillor; in a few towns, however, a certain power of choice is allowed to the municipal authorities—they may select one from a number of candidates presented to them by the government.

School-attendance is by law compulsory for eight years; the school-age beginning at the completion of the fifth year. But in most parts of Prussia, children, though allowed, are not compelled to attend till the completion of their sixth year. The school-period closes with confirmation. A register of all children of school-age is made up—usually at the police-office; every child is registered for a particular school; there, whatever his rank, he must attend, unless a dispensation be got for him from the *landrath*. When a dispensation is applied for, the parents must state the motives of the application, and the provision to be made for the child's education. All persons officially connected with schools are expected to use their influence to secure regular attendance; but failing moral suasion, there are other means of enforcing it. The schoolmaster keeps a list of absences, excused and unexcused. When a child's attendance is irregular, the board of managers admonishes its parent. If admonition—which in general is repeatedly resorted to—has no effect, a statement is sent to the police-office; the parent is fined a small sum for each day of the child's absence since the last admonition; and the fine can be levied by execution, enforced by imprisonment, or taken out in parish labour. It seems that very few children escape registration; but the regularity of the attendance—in general it is very regular—varies considerably in different districts; the execution of the law being strict or otherwise according to the temper of the people, their circumstances, and the vigilance of the school-authorities. There are no statistics by which the success of the law can be exactly tested. In some of the larger towns, the demand for child-labour and the growth

of pauperism are adding to the difficulty of enforcing it. Prussia has a factory-law requiring that every child employed in a factory shall attend school for three hours a day, and this law is strictly enforced.

Teachers of every class, public and private, have to pass two examinations. Certificates are of three degrees of merit—they may be marked 'very well qualified,' 'well qualified,' or 'sufficiently qualified.' The heads of examination are 'religion, the German language, the art of school-keeping, geography of Prussia, arithmetic and geometry, knowledge of natural objects, writing, drawing, singing and the theory of music, organ.' After the first examination, the candidate is eligible as an assistant or provisional master; he must serve in this capacity for three years before taking the second; he must pass the second within five years. The second examination is in the same subjects; but now most weight is given to the art of school-keeping. Of the subjects taught in primary schools, the principal is religion; the others are reading, writing, arithmetic, singing, and the elements of drawing. Incidentally, the teacher may communicate information about natural phenomena; about geography, beginning with that of the locality and the history of Prussia. The teaching was much more ambitious before 1854; before 1854, also, the normal schools, now limited to a meagre programme, were universities on a small scale, aiming at the mental training of their students, rather than at fitting them to teach elementary schools. The change is often ascribed, both in Prussia and out of it, to political motives, having been made by a party unfriendly to popular education; but eminent educationists defend and approve it. The schools, they say, are now attempting as much as can be thoroughly done in the time allotted for primary education, and are doing it thoroughly; while the showy teaching of former times, with its endeavour to develop the faculties, and to communicate knowledge, neglected the indispensable elementary instruction, and, as regarded the greater number of the scholars, was in no respect successful. The normal school training, it is said, now fits the teacher for his duties and his position in life; formerly, it rather unfitted him for them, while fitting him perhaps for something better. It is, however, admittedly a defect in the Prussian system that it offers to the humbler classes no opportunity of carrying their education beyond the point at which the elementary schools leave it. In some of the towns, there are improvement institutes, where young persons are taught in the evenings or on Sundays; but they attempt little, are badly organised, and are neglected by the school administrations. It should be stated that the town schools often teach somewhat more than is taught in country places—more geography, history, and natural knowledge—but this, though permitted, is not encouraged by the authorities. Grammar is entirely excluded from primary instruction. The only part of the teaching which is less than excellent is the writing: it has been stated that upwards of 50 per cent. of the recruits are unable to write—the art, never perfectly mastered, being lost, it must be supposed, through want of practice.

As regards religious instruction, the rule is, that the primary school is denominational—public schools are set apart, that is, for children of each of the religious bodies; the clergyman who has the charge of the school is the clergyman of the body to which it is appropriated. Besides the 'Evangelical Establishment,' in which Lutherans and Calvinists are combined, there are the Roman Catholics and the Jews to be provided for; of other sectaries, there are not 10,000 in all Prussia. The Lutherans and Calvinists are combined in the school as in the

church. Dissenters are allowed to withdraw their children from the religious instruction, and have it given by their own pastor. Any commune may establish a mixed school, if it so desire, and if the authorities permit; but, in practice, mixed schools are only to be found where it would be very inconvenient to establish a school for each body. In mixed schools, the teachers are chosen proportionately from each of the two great religious bodies; if there be only one teacher, it is, in some districts at least, customary that he should be alternately a Protestant and a Catholic. The experiment of mixed schools had a long trial in Prussia, and was found to be unsatisfactory, leading to attempts, or suspected attempts, at proselytism, and to parish squabbling. It has been abandoned, not so much from the wish of the government, as in deference to the feelings of the people, and to the demands of the Roman Catholic hierarchy. But the denominational system is more in accord with the part which the state assigns to religion in the school. The school, it is said, should be the organ of the church for training children to church-membership; school and church are expected between them to form the child into a man contented with his position in life. Religious teaching must be given by the master for an hour every day. In the Protestant schools, the master teaches the Lutheran catechism to Lutheran children; the Heidelberg catechism to the Reformed children. Scripture history is also taught; and hymns, from a prescribed collection, have to be committed to memory. The master is not allowed to expound the catechism; his duty is to see that the children learn it, and understand the words in which it is expressed. It is the clergyman who explains its doctrines to the elder children in preparing them for confirmation.

Any one may open a private school of any class in Prussia who can obtain a licence for the purpose from the government; but in a city, it must be shewn that the district in which the school is to be placed is insufficiently supplied with schools; and every private teacher must have passed the two examinations. Private schools are subject at all times to the inspection of the school-councillor, and are bound strictly to follow the regulations established for private schools. The larger towns in Prussia are not yet adequately supplied with public primary schools; private primary schools are therefore common in such places: in Berlin, they educate nearly half the children who are in primary schools.

Of the secondary and higher education in Prussia, a brief and general notice must suffice. It has already been stated that the superintendence of the secondary schools is undertaken by the school-councillor of the province; it is independent of ecclesiastical control. The larger communes and the towns are required to maintain middle schools, giving instruction of a higher order than is given in the elementary schools, a sound German education, and preparing boys for the gymnasium. These must be provided to the satisfaction of the authorities, according to the wants of the population. They are maintained, like the primary schools, by school-fees, local taxation, and these failing, the state treasury. Some of the larger towns maintain also secondary schools of a higher class; these are of two kinds—the real-school, and the gymnasium or grammar-school. In such towns, as stated already, the local management rests with the school-delegacy. There is, besides, a considerable number of real-schools and gymnasia which are entirely in the hands of the government. None of the real-schools take boarders; very few of the gymnasia do so. The gymnasium is a classical school preparing for

the universities. In the real-school, mathematics, scientific studies, and modern languages are substituted for the classics, and the instruction is designed to prepare the pupils, as far as possible, for the pursuits of life. The real-schools grant certificates to their pupils. The royal real-schools and the gymnasia (other than those maintained by the large towns) are under the management of the provincial school-councillor. Some of the older of those gymnasia have endowments, but the money necessary for their support is contributed by the state. Appointments to the schools are made by the school-councillor; he appoints the teachers, or nominates the leet out of which local authorities have to choose, in all the secondary schools. Teachers for all the schools have to pass two examinations. There are boards of examiners, appointed by the provincial government, which conduct the examinations; these boards also examine the students of the gymnasia, to test their fitness for the university. The university in Prussia is a teaching (or rather a lecturing), as well as an examining body, and grants degrees in four faculties—Theology, Jurisprudence, Medicine, and Philosophy. There are seven universities within the territory held by Prussia before the war of 1866; in two of these—Breslau and Bonn—there is a Roman Catholic as well as a Protestant institute of theology. The university affairs are administered by a commissioner appointed by the crown; all their regulations are prescribed, and all the appointments in them made by the state.

State-education in the United States.

In the United States, the education of the people is out of the sphere of the central government; it ranks among the domestic affairs of the several states, and it is chiefly in the Northern States—those from which, before the late war, slavery was excluded—that systematic attempts have been made to promote it. The central government has, however, in more than one instance endeavoured to assist education in the states, by providing for it endowments. In the states which contain waste lands, it puts aside, in every newly-surveyed township of six miles square, one square mile, for the support of schools within the township. The state becomes trustee of this land, or of the price obtained for it, which is usually called the Township Fund, and pays over the yearly income to the township when it has been settled. The central government, about 1836, had accumulated in its treasury a considerable balance, the surplus of its income over its expenditure during several years: this it apportioned *pro rata* among the states, reserving the right to reclaim it. This right has not been, and is not likely to be exercised; and in most of the Northern States, the income of the 'United States Deposit Fund' is applied to the support of education. Since 1864, by what is called the 'Agricultural College Act,' the central government has made a liberal offer of allotments of land to the states upon certain conditions, for the endowment of one or more institutions in every state, in which—whatever the other instruction may be—special attention shall be given to those branches of learning related to agriculture and the mechanic arts. Several states are preparing to avail themselves of this offer.

Every one of the Northern States has its common schools. Before the war, Kentucky, Missouri, and Louisiana had each some kind of school-system: at various points throughout the South, particular towns had established schools, always after the model set in the Northern States. The new state of Western Virginia has passed a

school-law since the conclusion of the war. In the Northern States, besides the endowments above described—both of which are possessed by most of the states—every state possesses a school-fund arising from various sources—sale of lands, taxation, penalties, and forfeitures—which is usually vested either in the state legislature or in a Board of Education. In one or two of the states, the income of this fund is considerable, but in general it is small. It is usually, but not in all the states, applied solely to the support of public schools, or of the normal schools which help to provide them with teachers. Apart from the influence exercised by means of this fund, the state usually promotes public instruction only by its legislation, by which it requires or enables local bodies to make certain provision for the education of children within their jurisdiction. Everywhere, the law leaves much, and usually the practice leaves everything, to the local bodies; and these come short of, or exceed the legal requirements according to the local interest in education and ability to pay for it. It is through the interest of the municipalities in education that very ample provision is made in the towns; it is through the force of example, and in deference to educational experience, that a certain uniformity of system prevails. There is a close approach to uniformity both in the law and in the practice of the several states; and a description of the system of one state will be approximately true of that of other states. The Massachusetts system is fittest to be selected for description, as being the oldest, the most celebrated, that which on our side of the Atlantic is most identified with the common schools, and perhaps on the whole the most successful. Some of the principal variations from it will be noted.

In 1642—twenty years after the landing of the *Mayflower*—the Massachusetts colonists passed a law requiring every citizen, under a penalty of 20s., to teach his children and apprentices, or have them taught, to read perfectly the English language. Five years later, they passed another law, requiring, under penalty, every township containing 50 householders to support a teacher to teach their children to read and write; requiring every township containing 100 householders to maintain a grammar-school capable of fitting youths for the university. The present law is different, if not less liberally conceived. The change was made by numerous steps, and was probably forced on by the circumstances of the community. The law, as it now stands in the revised statutes of the state, provides that in every township the inhabitants shall maintain for at least six months in the year a sufficient number of schools for all the children of the township. The teachers are to be of competent ability and of good morals, and they are to teach orthography, reading, writing, English grammar, geography, arithmetic, the history of the United States, and good behaviour. Other subjects—algebra, vocal music, drawing, physiology, and hygiene—are to be taught or not at the discretion of the local committee. Every township may, and every township containing 500 householders must, also maintain for ten months in the year a school which shall give instruction in general history, book-keeping, surveying, geometry, natural philosophy, chemistry, botany, the civil polity of Massachusetts and of the United States, and the Latin language. And in every township containing 4000 inhabitants, the teacher must be competent to instruct in the Greek and French languages, in astronomy, geology, rhetoric, logic, intellectual and moral sciences, and political economy. Moreover, any township may establish schools for children over 15 years of age, determining the instruction

to be given, and appropriate money for their support. The compulsory part of the law is supported by penalties, but it is said that there would be difficulty in enforcing them; at anyrate, they are not enforced. It is also provided that every child between 8 and 14 must be sent to school for at least 12 weeks in a year: the penalty for breach of this provision is 20 dollars, but the idea of enforcing it seems never to have been entertained; its existence even is not generally known. The law does not permit school-fees, or, as they are called in America, rate-bills. There seems to be no fund arising from waste lands in Massachusetts; and the township raises the necessary funds by a tax upon property—the personal property of the inhabitants and the capitalised value of their real property situated within the township. The amount of the rate is by the law left wholly undetermined: it is determined by the householders at their annual meeting. The state endeavours to influence the townships to make a liberal provision by means of the school-fund, a share of which is given to every township which has made its returns to the Board of Education, and has spent not less than at the rate of a dollar and a half per head for all the children of the township. The school-fund contribution is very small—less than a quarter-dollar for every child; but it is said to have an excellent influence upon the rural townships. No doubt, the publication of the returns made to the Board of Education tends to spur on the backward districts.

The management and control of all the public schools of a township are placed in the hands of a school-committee, consisting of any number divisible by three; the members of this committee hold office for three years, and one-third of them are elected annually at the annual meeting of the township. The committee have the supervision of the schools; and it is among their duties to see that no book calculated to favour the tenets of any particular sect of Christians shall be used in the schools, and to require the daily reading of some portion of the Bible in the common English version. Any township, by its public meeting, or a city, by its city-council, may require the committee to appoint a paid superintendent of schools: when this is not done, the members of the committee receive a small allowance for the time during which they are engaged upon the school-affairs. But, moreover, any township may, at a meeting called for the purpose, resolve to divide itself into districts for the support of its schools. If this be done, the township names for each district a 'prudential committee,' consisting either of one or of three persons, resident within the district, which is charged with providing and keeping in repair the school-house, at the expense of the district, and, if the township so determines, with the duty of selecting and contracting with the teachers. The district determines the amount to be raised by it for the building, or repair or furnishing of its school; this is collected by the township collector, and handed over to the district-committee. The school-committee retains its functions of management, except so far as they have been made over to the districts; and hence, there is a double management of the schools, which is found to be attended with inconveniences. The division into districts, too, is said to have led to an unnecessary multiplication of schools in country places: people scheme to have the township so divided that there may be a school in their neighbourhood—there are therefore more schools than are needed, and more than can be maintained in efficiency. The school-committee—in cities, the school-superintendent—examines the teacher before his appointment, and grants him a certificate, which

remains in force for a certain time. There are three classes of certificate—one valid for six months, another for twelve, a third for two years. The common schools of a township are open to all children resident therein between five and fifteen years of age: none are to be excluded on account of race, colour, or religious opinions; and it has been held that a child unlawfully excluded may recover damages therefor in an action of tort.

In New York, in Pennsylvania, and in most of the Western States, large municipal powers are possessed by the county, and the county shares with the township the management of school-affairs. New York has a state superintendent, whose power over the schools is considerable. In that state, it is the school-commissioner of the 'Assembly District' in which the township lies who divides the township into school-districts; and it is the district which determines the school-tax: the township is almost completely ignored. In New York, Ohio, and Illinois, it is by county officials that teachers are examined and certificated. In New York, Rhode Island, and Connecticut, 'rate-bills'—that is, school-fees—are allowed, and are usually levied. Several states besides Massachusetts make school-attendance compulsory: in most of the states, there appears to be some provision against 'truancy,' but it appears that attempts are not made to enforce the law except occasionally, in the case of homeless, wandering children, who are liable, in lieu of a fine, to be sent to reformatory schools. It has been calculated that in the city of New York (pop. 800,000) there are nearly 100,000 children who do not go to school—though in no city is there a better or ampler provision of common schools.

As might be expected, the school-laws work badly in country districts. The householders are disposed to be satisfied with any kind of school, provided it be cheap, and within easy reach of them; and the multiplication of schools by the district-system, makes it almost unavoidable that an insufficient sum should be spent upon each school. The teachers—a vast majority of whom are women—being wretchedly paid, are badly qualified; they are constantly changing; scarcely any intend to make teaching their occupation for life. Few of them have been trained for their work—the normal schools which exist being utterly inadequate to supply the demand for teachers; and the examination by a rural school-committee affords but a slender guarantee of competency. The teacher is usually 'boarded round' among the farmers of the district, and is said to be treated by them with much observance; but his income—putting a money-value upon the board—has been estimated at an average of about 50s. a month, and that only during the time that the school is open. In 1864, in 84 townships of Massachusetts—more than a fourth of all the townships in the state—the schools were kept open for less than the statutory period of six months. The teaching is said to be wonderfully good, considering the scanty pay given; but where the vacations last for more than six months, and the teacher is changed almost every term, thorough and systematic instruction is scarcely possible. It is in the towns that the working of the school-law has been creditable and successful. Through the high public spirit of the municipal bodies, and the great importance attached to education, the support of the common schools is in general most liberally provided for.

In the towns, there is usually a superintendent of schools, by whom, under and in co-operation with the general and district school-committees, the schools are inspected, and the character of the instruction determined; by him the examination of

the teachers also is conducted. Of the schools, there are four classes—primary, intermediate, grammar, and high-schools or academies. Children usually enter the primary school about 5 or 6; the grammar-school between 8 and 9; the high-school between 12 and 13 years of age. They are not promoted from one class of school to another without undergoing an examination; the intermediate schools, where they exist, are intended for those who are too old to be at the primary school, and too backward to enter the grammar-school. To be admitted to a grammar-school, a child must be able to read at first sight easy prose, to spell common words of not more than three syllables, and to have acquired a slight knowledge of arithmetic. For admission to the high-school, the usual requirements are ability to read correctly and fluently, an acquaintance with the simple rules of arithmetic, and some knowledge of geography and grammar. From these tests may be inferred the average proficiency expected to be attained by children leaving the primary and the grammar school respectively. In the grammar-schools of Boston, the programme of studies consists of spelling, reading, writing, arithmetic with book-keeping, geography, English grammar, the history of the United States, natural philosophy, drawing, and vocal music: this is nearly the usual programme; but in New York and one or two other states a little more is attempted. Between the high-schools or academies in the various states, there are considerable differences. In the city of New York, for example, the Free Academy has pretensions to the rank of a university, and grants degrees in arts and science (Bachelor of Arts, Bachelor of Science, Master of Arts) to students who have completed with credit the curriculum of five years. But, in general, the high-schools are schools of secondary instruction, intended to prepare youths for the university—instruction being given in the classical languages, mathematics, the sciences, history, and the English language and English literature. The usual curriculum is one of four years; and the students are not required to study all the subjects taught in the school. At Boston, where boys are admissible to the Latin high-school at 10 years of age, the curriculum lasts for six years. There are high-schools for girls as well as for boys, the programme of instruction being the same in both. At Boston, the curriculum at the girls' high-school lasts for three years; and pupils at admission must be between 15 and 19 years of age. Boston possesses, besides its Latin high-school and its girls' high-school, an English high-school, said to be admirably planned and conducted. The instruction in it closely resembles that given in the real-schools of Germany, including French and German, and various sciences, with their application; being intended to enable boys to complete a sound English education, and to prepare themselves for commercial life. Great complaints are almost everywhere made—Boston seems to be exceptional in this respect—of the irregularity of the attendance at the primary schools. It is estimated that in most states not much more than half of the children pass from these to the grammar-schools; but a trifling proportion of the grammar-school pupils enter the high-schools, and of these, only a small fraction persist to the end of the curriculum. All high-schools grant certificates of graduation to pupils who have creditably gone through the course of study. The study of the classics does not, even in the most pretentious institutions of this class, seem to be carried very far, much more attention being given to mathematics and natural science. In Boston—in many respects the most favourable example that could be taken—there were, in 1864,

32,814 children of school-age—between 5 and 15; of these, 26,960 were in school, the average attendance being 24,617. The number enrolled at the three high-schools was only 725, and the average attendance 691. The number of students who complete the five years' curriculum of the New York Free Academy seldom exceeds fifty. Among the wealthy, there is said to be a growing disinclination to make use of the common-schools: their children are usually sent to private academies. The only serious opposition to the non-religious character of the common-schools comes from the Roman Catholic clergy; but it is stated that there is a growing feeling upon this subject among some of the other religious bodies. In many of the New York schools, in which the majority of the children are Roman Catholic, clerical influence, insufficient to impress upon the education the religious character which it would approve, has obtained, with the tacit assent of the school-authorities, the disuse of the daily Bible reading which the law prescribes.

The primary and grammar schools are most frequently mixed schools—that is, they admit boys and girls; in the teaching, however, the sexes are kept apart. The teachers in primary and grammar schools, even in the towns, are usually women; but in Boston the principal of a grammar-school is always of the other sex. The schools are in towns always *graded*—divided, that is, into classes composed of those who are at the same stage; each grade forms a separate department of the school, and is taught by a separate master. The usual number of pupils allotted to a teacher is in the primary schools about 50; in the grammar-schools about 35. This system of grading is a cheap system, because it enables a teacher to take charge of a large number of pupils; but it is said to lead to a want of thoroughness in the instruction, the teaching being addressed to the class rather than to the individual members of it. Want of thoroughness seems, indeed, the besetting sin of American teaching, which aims too much at communicating knowledge, not sufficiently at developing capacities. In the primary and grammar schools, the education costs from 25s. to 30s. per head; in the high-schools, from £6 to £10 per head.

Statistics of National Education.

The proportion of children attending school—i. e., enrolled in school-registers—to the whole population of the countries under mentioned may be approximately stated as follows: England, 1 in 7·7; Scotland, 1 in 6·5; Prussia, 1 in 6·27; France 1 in 9; Holland, 1 in 8·11; Belgium, 1 in 11; Northern States of the American Union, 1 in 4·5; Switzerland, 1 in 7; the minor Protestant states of Germany, 1 in 6·7. These figures must not be taken as indicating the comparative diffusion of education in the countries named; Holland, for example, where the proportion of children at school is comparatively low, is at least unsurpassed in this respect by any European country. Nor are they to be relied on as indicating, with anything like exactness, the comparative proportions of children actually attending school; for the proportion of the children enrolled, which on the average is in actual attendance, varies in different countries. The high proportion enrolled in the American States, for example, is in a great measure explained by the shortness of the school sessions in country districts, by the large number who attend only during the winter sessions, and whose attendance is on that account spread over a greater number of years. The proportion stated for England is that given by the Education Commissioners in 1861; since that time, no doubt, there has been a slight improvement. According to the census of 1861, 1 in 6·37

of the population of England consisted of school-children; but particular inquiries have shewn that in this instance the census tables are not to be relied upon. On the other hand, it has been lately estimated by a good authority, Mr W. E. Forster, M.P., that less than 1 in 10 of the population of England is at school. Lest any wrong inference should be drawn from the figures more favourable to England and Scotland which have been stated, it should be borne in mind that averages conceal the condition of the worst parts of a country. And, in fact, the diffusion of education in England and Scotland is exceedingly unequal. In Scotland, the variation in the school attendance runs, according to the recent Royal Commission, from 1 in 4 of the population in the best districts, to 1 in 15, 1 in 20, and even to 1 in 30 in the worst. Attempts have sometimes been made to estimate the percentage of people in different countries able to read and write; but such estimates are mere vague conjectures, and it would be worse than useless to set them down.

See the numerous authorities quoted or referred to in the Reports of the assistant-commissioners appointed to inquire into the State of Popular Education in England, vol. iv. containing 'Reports of the Assistant-commissioners on the State of Popular Education in Continental Europe,' and being vol. xxi. part iv. sess. 1861; the second Report of the Scottish Educational Commissioners, 1867, and the Reports of the several Assistant Educational Commissioners accompanying the same; the Statistical Society's Quarterly Journal for March 1867; Horace Mann's on Education in European Countries; Fraser's Report on American (U. S. and Canada) Schools (This report, published in July 1867, forms part of the Report of the Schools Inquiry Commission appointed in 1865. The report is to extend to 21 vols., and will be the richest repertory of information on the subject of education ever issued. The introductory volume was presented to parliament in March 1868, and the others were to follow soon); Cousin on German and Dutch Education; M. Block's Abstract of Public Documents relating to Education in France; *L'Instruction du Peuple*, par Pierre Tempels (Bruxelles, 1865); *Statistische Nachrichten über das Elementar Schulwesen*, an official return, which gives a complete survey of elementary education in Prussia to the end of 1864; *Congrès International de Bienfaisance de Londres, Session de 1862*; and *Rapport et Discussion sur l'Instruction Obligatoire*, containing an important discussion on compulsory education.

NAUTILUS PROPELLER is the best known among many names given to a mode of propelling steam-vessels by means of a horizontal wheel within board, instead of a paddle or a screw on the outside. Hydraulic or Turbine propeller would either of them be a better designation. Engineers thought of this mode of propulsion generations ago, and patents have been taken out for inventions relating to it by Toogood, Hayes, Rumsey, Linaker, Hall, and others; but the most successful attempts to realise it have been those of Mr Ruthven. He constructed a small boat, 9 feet long, in 1839 (tried on the Union Canal), and a vessel, 40 feet long, in 1844 (tried on the Forth), to test the principle; each was worked by a small steam-engine, and provided with the hydraulic apparatus. In 1849, Mr Ruthven made improvements in the apparatus, and introduced them in a vessel, 30 feet long, tried upon the Thames. In 1851, he placed a boat in the Great Exhibition. In 1853, a vessel on this principle, called the *Albert*, was built in Prussia by M. Sydel, the machinery being supplied by Mr Ruthven. She plied on the Oder as a passenger-steamer for many

years, and illustrated favourably some of the characteristic features of the nautilus system. The term of Mr Ruthven's patent expired, however, before the invention had worked its way into use in England; and the Privy Council, in 1863, gave a further term of ten years. He afterwards began building a vessel to be called the *Nautilus*; while the Admiralty authorised the commencement of the gun-vessel *Waterwitch*, both to be worked on the Ruthven principle.

The *Nautilus* was first tried on the Thames in April 1866. It is fitted with two steam-engines, of 10 (nominal) horse-power each, with cylinders of 17 inches diameter, and 2 feet stroke. Water is admitted through apertures in the bottom of the vessel into a water-tight iron case or compartment. In this case is placed a horizontal turbine-wheel, 7 feet in diameter, acted on from a vertical shaft connected with the steam-cylinders. The wheel is divided into compartments by plates or radii of peculiar curvature, and is placed below the water-line of the vessel, so as to be always immersed. Two pipes extend from the wheel-case, one to either side of the vessel, where they emerge nearly at midship. Each pipe terminates with nozzles, 10 inches in diameter, placed outside the vessel at right angles to the pipes; insomuch that each side of the vessel has a nozzle pointing ahead and another pointing astern. A valve is fitted to each pipe, at its junction with the nozzles, to open the passage to one nozzle and close it against the other; and the movement both of the starboard and the larboard valves can be governed from a raised deck built over the engine-house. The wheel-case is always full, or nearly full, of water, which enters through the apertures in the bottom of the vessel. When the wheel is made to rotate horizontally by the steam-engines, water is drawn in through the hollow axis, and expelled at the periphery by centrifugal force; it can only find an outlet through the two pipes, and then through the nozzles which terminate them. Supposing the nozzles pointing astern to be open, and those pointing ahead to be closed, the water of the river or sea, resisting the outrush of the water from the nozzles, propels the vessel forward; when the forward nozzles are open, and the hinder ones closed, the vessel is propelled backwards, or driven astern. The captain, standing on the raised deck, and commanding both valves, can close the fore-nozzles, and open the aft, which makes the vessel go ahead; he can open the fore, and close the aft, which makes her go astern; he can open one fore-nozzle, and close the other, which makes her turn. By this remarkable action, the officer can steer the vessel without any rudder whatever, although a rudder is, for other reasons, useful; and the vessel can turn completely round in a smaller space and a shorter time than an ordinary steamer. The exit of the water from the nozzles is a little above sea-level, a plan found to be better than actually immersing them. In one of the trial-trips of the *Nautilus*, with strong wind and tide urging her on, and going at full speed, she was stopped dead in less than ten seconds, and in about a quarter of her length, by simply reversing the valves.

The performance of the *Nautilus* was so satisfactory as to lead the Admiralty to expedite the finishing of the *Waterwitch*, an iron-clad gun-vessel of 778 tons and 160 horse-power. In this vessel, the wheel is 14 feet diameter, the curved radii 12 in number; it rotates (at full engine-power) 39 times per minute, in a wheel-case 19 feet diameter; the pipes from the case measure 27 inches by 25; the brass nozzles, 24 inches by 18, are continued along the outside of the vessel, 8 feet on each side of the

centre; the lower lips of the discharge-nozzles are 3 inches below water-line, the remainder of the aperture being above water. The trial-trip, in October 1866, was successful in regard to speed, as compared with the *Viper* screw gun-vessel, of similar tonnage and horse-power.

During 1867, the *Nautilus* and *Waterwitch* were subjected to other tests besides speed, in relation to the following advantages claimed for the turbine principle. 1. With this wheel there cannot be any 'slip,' which occasions a certain loss of power in the paddle and the screw. 2. The power being uniform and continuous, the motion of the vessel is likely to be smooth, little affected by trembling or vibrating. 3. The propelling power being unaffected by a storm, there will be no reaction on the engines from the motion of the vessel in a heavy sea. 4. The vessel is rendered independent of her rudder, as she can be turned on her centre by the propeller alone, without the helm and without steerage-way. 5. The propeller, being placed within the vessel, is less exposed than the screw or the paddle to injury from shot, fouling, or accidents of war. 6. The propeller, on account of its action being independent of the draught of water, will work effectually so long as there is the barest depth of water for the vessel to float in. 7. Should the vessel spring a leak, or be pierced with shot, the regular supply of water can be cut off from the wheel, and the leakage-water used instead, thereby pumping the hold by the very act of propelling the vessel. 8. From the peculiarities of action, the hydraulic propeller is likely to present great facilities for manœuvring a ship-of-war under steam.

NEEMU'CH, or NIMACH, a town of India, in the territory of Gwalior (q.v.), near the north-western border of Malwa, 320 miles south-west from Delhi, on a slightly elevated ridge rising from a well-cultivated plain. It is 1476 feet above the sea. The native population of the town is only about 4000; but N. has acquired importance on account of a British cantonment established here in 1817. Prior to the sepoy mutiny of 1857—1859, the officers' quarters comprised about 80 bungalows, beautifully situated among gardens; but all, except a single bungalow, were destroyed in 1857 by the mutineers, who massacred the Europeans, and kept possession of the fort for some time, till it was captured by Brigadier Stuart after a siege of fourteen days. The situation of N. is regarded as one of the most healthy in India; the climate is agreeable, the nights cool even in the hot season, the winter seldom so cold as to make fires requisite, and frost very rare.

NEGAPATA'M, a town of British India, in the presidency of Madras, and district of Tanjore, 124 miles south-south-west from Madras, on a small estuary of one of the many small southern mouths of the Cauvery. The manufacture of cotton and silk fabrics was, in former times, extensively carried on here, but has greatly declined in consequence of the cheapness of British goods. A chief branch of industry is the expression of oil from the cocoa-nut and from oil-seeds. There is a considerable trade with Ceylon. The harbour is suited only for small coasting-vessels; but measures are in progress for its improvement. It is proposed to connect N. by railway with Trichinopoly, 80 miles distant. N. was the capital of the Dutch possessions in India, but was taken by the British in 1781. Pop. 10,000.

NELLORE, a town of British India, capital of a district of the same name, in the presidency of Madras, situated on an elevation on the right bank of the Northern Pennar, 20 miles from its mouth, and 95 miles north-north-west from Madras. It is

irregularly built, and the population in some places much crowded; but there are some good streets. The abundant supply of water contributes to the health of the town. N. was formerly an important fortress. It is a curious circumstance that, in the end of last century, a pot filled with Roman gold coins and medals—chiefly of Trajan, Adrian, and Faustina—was found under the ruins of a small Hindu temple at Nellore. Pop. 20,000.

NELSON, the capital of a province of the same name, in New Zealand, is situated at the north end of the Middle Island, at the mouth of the Maitai, a small river, and at the head of a large bay called Blind Bay. The situation is very beautiful, on a flat, hemmed in by rugged hills and amidst almost tropical luxuriance. The harbour, however, only admits vessels of 500 tons at high water, and this circumstance has much retarded the progress both of the town and the settlement. The centre of the town is a hill rising 40 feet above the surrounding streets, and laid out as a square with an Episcopal church in its centre. N. was founded in 1841. The number of vessels which entered and cleared the port in 1865 was 192, with a tonnage of 62,320. Value of the imports for the same year, £400,258; exports, £117,143. Pop. (1863) 5000.

NERIA'D, a town of British India, in the presidency of Bombay and district of Kaira, on the route from Baroda to Ahmedabad, 38 miles north-west from Baroda, on a feeder of the Sabarmati. It is the chief town of an extensive and well-cultivated tract, which produces much tobacco, and contains many prosperous towns and villages. Pop. 40,000.

NERVOUS DISEASES OF AN OBSCURE NATURE AND NERVOUSNESS. Although the most important affections of the nervous system, as chorea, convulsions, epilepsy, hydrophobia, hypochondriasis, hysteria, neuralgia, paralysis, spasms, and tetanus, have been considered in special articles, there is an infinite variety of (often evanescent) forms which the diseases of the nervous system assume, some of which we propose now to consider.

These nervous affections are almost solely confined to women, and most of them may be regarded as modified forms of hysteria. *Simulated Pregnancy*, or, as the French physicians term it, *Nervous Pregnancy*, is an affection of not very rare occurrence. The abdomen gradually enlarges, the catamenia are suppressed, and sickness, enlargement of the breasts, with the other symptoms of pregnancy, supervene (as far as they can be recognised by the non-professional observer), and it is only the non-appearance of the infant at the expected period that leads to a suspicion of the true nature of the case. The diagnosis of such a case is extremely difficult, and the most celebrated accoucheurs have been deceived. We commence with this extreme instance, as being singularly illustrative of the power which a perverted action of the nervous system may impress upon certain persons. The somewhat allied cases in which patients persist in fancying themselves pregnant in opposition to the opinion of their medical adviser (as the well-known case of Queen Mary, so admirably drawn by Froude), are far more numerous. The intestines are often implicated in cases of a deranged condition of the nervous system. The excretion of gas from the intestinal mucous membrane is often much increased in the class of patients commonly called nervous. The rattling sounds produced by the movement of the gas—scientifically known as *bomborygmi*—are sometimes so loud as to prevent the patient from entering into society with comfort; and sometimes the mere fear of the occurrence of these sounds is

sufficient to induce them. A depraved appetite, scientifically known as *pica*, is a common symptom of deranged nervous system both in chlorotic young women, in whom the catamenial discharge is not well established, and in pregnant women. See MORBID APPETITES. The not very rare cases of fasting women and girls belong to the same category. All these cases, however, ultimately undergo detection.

Dr Parry and other physicians have described cases of morbid sensibility of the mucous membrane of the pharynx, in which the muscles of the larynx are called into violent action if the patient takes a sip of water or other fluid. Such cases so strongly simulate hydrophobia, that they are described as hysterical hydrophobia.

Passing on to the special modifications which an abnormal state of the nervous system impresses on the organs of circulation, we have nervous palpitation of the heart, which may readily be distinguished from palpitation dependent on change of structure by due attention to symptoms. There is a peculiar form of abdominal pulsation, due solely to nervous influence, which may not very unfrequently be felt on pressing the hand on the patient's abdomen. It has in many cases been mistaken for aneurism.

The nervous symptoms implicating the respiratory organs are not only the most common of any, but are alarming and urgent, and may be readily mistaken for indications of serious inflammatory or organic disease. Nervous asthma, which is supposed to depend upon a spasmodic constriction of the bronchial tubes, is too well known to require comment. Women suffering from a deranged condition of the nervous system sometimes present symptoms of what may be termed nervous catarrh—such as a copious flow of tears, free discharge from the nostrils, and constant sneezing. Such cases are often periodic. They may be treated with preparations of iron, and are sometimes at once checked by a pinch of snuff. There are various forms of cough due mainly to nervous irritation, the difference in the character of the cough probably depending on the spot which is the seat of irritation. Thus, we hear of *spasmodic* cough, which is often accompanied by much straining and convulsive agitation, and somewhat resembles whooping-cough; *ringing* cough, accompanied by dyspnoea and hoarseness, or loss of voice; *barking* cough, often arising from irritation of the ovaries, &c. Such coughs as these are aggravated by depleting measures, ordinary cough medicines, &c., and usually disappear under the use of tonics.

The nervous affections of the motor system are conveniently grouped by Dr Laycock under three heads—(1) the first including those cases in which there is paralysis or spasm without distortion; (2) those in which distortion follows cessation of muscular equilibrium, as in the various forms of club-foot; and (3) paroxysmal affections. The best example of the *first* class is hysterical paralysis of the lower extremities, of which Sir Benjamin Brodie long ago wrote as follows: 'I have known not a few, but very numerous instances of young ladies being condemned to the horizontal posture, and even to the torture of caustic issues and setons, for several successive years, in whom air, and exercise, and cheerful occupations would probably have procured a cure in the course of a few months.' A notice of such cases as these may be found in the article HYSTERIA. Paralysis of a lateral half of the body, or of one limb only, may also be merely a manifestation of hysteria. The *second* class is well illustrated by the following case, which is reported by Mr Shaw. A

young lady who had suffered from a train of symptoms indicative of a disturbed nervous system, had the ankle so turned round that she walked on one side of the foot. The knee was also bent outwards, and the spine was becoming distorted. Sir Charles Bell, who saw her in consultation, regarded the case as one of wilful deception, and in a year's time his diagnosis was completely established, scarcely any trace of lameness being apparent. Many of the joints—as the knee, hip, &c.—may be the seats of purely neuralgic symptoms, which so closely simulate organic disease of the cartilages, as to lead to the removal of the limb. Carmichael, Brodie, and others have recorded cases in which this terrible mistake has been made by experienced surgeons. Spinal irritation, or spinal tenderness, is a mysterious affection, whose diagnostic value is not very definite, as it may arise from a large number of distinct conditions, as, for example, disease of some part of the spinal cord, uterine disease, chronic disease of the intestinal viscera, &c.

One of the most anomalous affections of the nervous system ever recorded is described by Mr Holden in the *St Bartholomew's Hospital Reports*, 1867, vol. iii., pp. 299—305. The patient is a bright-looking boy about 12½, who, as he lies reading in bed, presents every appearance of perfect health: all that he complains of is what he calls his 'bump,' which is about the size of a hen's egg, and lies on the right side of the neck, just above the shoulder. If the 'bump' be touched, even most gently, the boy instantly loses all consciousness, and becomes deaf, dumb, and blind, while his body becomes arched like a bow, and is supported only by the back of the head and the heels, while his arms are rigidly extended. He may be pinched or pricked, but shews no sign of sensation. After remaining in this state for somewhat less than a minute, he draws a deep long breath, which is followed by a deep sigh. Instantly the spasm ceases, and the body falls, seemingly lifeless, on the bed. After two other similar sighs, which occur in a few seconds, the boy awakes as if from profound sleep, and in a few minutes is none the worse for what he has gone through. Whenever the bump is touched—even when the boy is fast asleep—the same phenomena occur. (It has been found that, on touching the backbone in the dorsal region, the same series of events happen.) By continuous gentle manipulation of the bump, the boy has been kept unconscious for twenty minutes. Another and even more remarkable phase of the boy's affection is his crowing and barking fit, which takes place every day at the same time, almost to a minute. See the Reports above cited.

With this illustration, we close our remarks on what may be termed *Anomalous Nervous Affections*. With regard to *Nervousness*, which also stands at the head of this article, we may observe, that it is a word pertaining rather to the vocabulary of the patient (and pre-eminently of the female patient) than of the physician. It is usually understood to indicate a condition of which a *restless* mobility, with or without an undue excitability of the nerves of sensation, is the chief characteristic. For further information on this subject, the reader is referred to Dr Laycock's various works, and to Romberg *On Diseases of the Nervous System*, 2 vols, translated by Dr Sieveking.

NEST-BUILDING APES. Reference was made, but with some hesitation, in the article GORILLA, to certain new species of apes of the same genus with the chimpanzee and gorilla, said to have been discovered by M. du Chaillu in Western Africa. The complete vindication which has since taken place of that traveller's reputation as a truthful

and trustworthy observer, makes it necessary to give some further notice of these now unquestioned discoveries, exceedingly remarkable on account of the habits of some of the animals. To protect themselves from the rain, they construct nests, or rather umbrellas, among the branches of the trees, of long branches and leaves laid one over the other very carefully and thickly, so as to be 'capable of shedding water.' The branches are fastened to the tree in the middle of the structure by portions of the stems of twining shrubs, abundant in these forests. When the leaves dry, so that the structure no longer keeps out the rain, the owner builds another shelter; and Du Chaillu says this happens

Nest-building Ape (*Troglodytes calvus*).

once in ten or fifteen days. The nest-building ape (*Troglodytes calvus*, called Nshiego Mbouve by the natives) is nearly four feet in length. Du Chaillu supposes this ape to rest all night on a projecting branch under its nest or umbrella, with an arm round the stem of the tree for security. The nests are generally constructed about 15 or 20 feet from the ground, and invariably on a tree which stands a little apart from others, and which has no limbs below the one in which the nest is placed, probably in order to safety from serpents and other animals. These apes inhabit the most lonely parts of the forests. The nests are never congregated together, so that this ape does not seem to be gregarious. It feeds on fruits.—Du Chaillu discovered a second species of nest-building ape, on his second visit to the Ogobai, very similar to the *Troglodytes calvus*, but which constructs its nest in a somewhat different fashion. It is called Nshiego Nkengo by the natives. It makes its nest or shelter at the height of about 20 or 30 feet from the ground, by bending over and intertwining a number of the weaker boughs, the foliage of which forms its protection from rain.

NEU-CHWANG, or YING-TSZE, a town of the Chinese Empire, in Manchuria. It stands on the left bank of the river Liaou, about 25 miles from its mouth, and in lat. 41° N., and long. 122° 30' E. The Liaou, which falls into the Gulf of Liaou-tong, at the head of the Yellow Sea, is navigable for sea-going vessels to N.; and N. is therefore regarded as a seaport, and is one of those opened to foreign trade by the treaty of Tientsin. A British consul resides here; but the trade is as yet inconsiderable, and only to Chinese ports.

NEUILLY (sometimes called NEUILLY-SUR-SEINE, to distinguish it from several much less

important places of the same name), a town of France, in the dep. of Seine, on the right bank of the river Seine, immediately to the north of the Bois de Boulogne. N. may now be regarded as a suburb of Paris, with which it is connected by several streets, or roads, lined with numerous villas. Here, near the Seine, and in a large and beautiful park, formerly stood the Château de Neuilly, built by Louis XV., and the favourite residence of Louis Philippe, which was burned at the revolution in 1848. The park was also then divided into lots for sale, the consequence being a rapid increase of the number of houses in Neuilly. N. has manufactures of porcelain and starch, chemical works and distilleries. Pop. (1866) 16,475. When Louis Philippe abdicated, and took refuge in England, he assumed the title of Count de Neuilly.

NEU'MÜNSTER, a prosperous manufacturing and market town of Holstein, on the Schwale, one of the head-waters of the Stoor, and on the railway between Altona and Kiel, 19 miles south-by-west from Kiel. There are large woollen and linen factories, tanneries, dye-works, and breweries. Pop. (1864) 7797.

NEUSTETTIN, a town of Prussia, in the province of Pomerania, 92 miles south-west from Danzig, on the southern shore of the Vilm See. It is the capital of a circle, and a place of some importance. Pop. (1864) 6219.

NEUTRA, a town of Hungary, the capital of a county of the same name, on a river of the same name, 72 miles north-north-west from Pesth. N. is a very old town, having been the residence of a Moravian prince in the 9th c., before the Magyar invasion. Weaving is carried on to some extent, and N. being not far from the Moravian frontier, has a considerable transit-trade. Pop. 9267.

NEVIA'NSK, a town of Russia, in the government of Perm, 50 miles north from Ekaterinburg. It is on the eastern or Siberian side of the Ural Mountains, and stands on the Neiva, the waters of which flow by the Tobol and the Irtish to the Obi. The district around N. is famous for its mineral wealth, particularly for its productiveness of gold, copper, and platinum. N. has a mint, the tower of which is remarkable as leaning even more than the celebrated tower of Pisa. Pop. 18,000.

NEW'CHURCH, a very thriving town of Lancashire, England, 19 miles north from Manchester, in Rossendale, not far from the source of the Irwell. It has recently and rapidly risen to its present importance. There are numerous cotton and woollen manufactories, employing many operatives. Coal is also wrought in the neighbourhood, and there are numerous large quarries of excellent freestone. Pop. (1861) 3115. The neighbourhood is very populous, abounding in manufactories and other public works.—Not much more than a mile to the west of N., is Rawtenstall, a large village, now almost a town, and rapidly increasing.

NGAN-KING, a large and wealthy city of China, the capital of the province of Ngan-whi. It stands on the left bank of the great river Yang-tze-Kiang, 190 miles south-west from Nankin. The surrounding country is highly cultivated, and very densely peopled. The mineral riches of the neighbourhood are also considerable. N. is a place of busy trade, great part of the goods intended for Nankin passing through the hands of its merchants. The trade is carried on by means of vessels on the river. Porcelain and cloth are among the principal articles of trade.

NIARE (*Bos brachicheros*), the wild ox or buffalo of tropical Western Africa, is in size and weight

about equal to the smaller breeds of British oxen, but of greater strength. The head is rather small, the muzzle black, the ears long and pointed, and fringed with beautiful silky hair, several inches long. The horns are 10 or 12 inches long, curved backwards, and sharply pointed. The animal is gracefully proportioned, having nothing of the clumsiness of the common buffalo. The body is covered with a coat of thin red hair. The tail is tufted at the extremity with black hair

Niare (*Bos brachicheros*).

several inches long. Herds of these oxen were seen by Du Chaillu in the open or prairie lands to the south of the mouth of the Ogobai. They are shy and fierce; if wounded, they turn upon the hunter with terrible fury. No attempt seems yet to have been made to domesticate this animal, which is probably very capable of it, and might be found more suitable than other oxen for warm climates.

NICARAGUA, or RIVAS, a town of the republic of Nicaragua (q. v.), Central America, on the western shore of the Lake Nicaragua (q. v.), 35 miles south-south-east from Granada. It is not a place of much commerce, the commerce of the lake being chiefly carried on by Granada. Pop. 8500.

NICHOLSON, JOHN, British general, one of the most distinguished of the later school of Indian soldiers, was born in Dublin, 11th December 1821. His father, a physician of considerable reputation in that city, died when the boy had just completed his 8th year. By his mother, a woman of strong sense and much practical piety, he was carefully educated; and from her he seems to have inherited or imbibed a certain religious gravity and earnestness of character which was early noted in him, and continued to distinguish him through life. Through the influence of her brother, Sir James Weir Hogg, an Indian cadetship was obtained for him; at the age of 16, he arrived in Calcutta, and was soon after posted to the 21st Native Bengal Infantry, then stationed at Ferozepore. In 1840, his regiment was ordered to Ghizni in Afghanistan, where two years after, in the disastrous insurrection which avenged our occupation of the country, it was compelled to surrender to the enemy. After a time of miserable captivity, he regained his liberty, and joined the relieving army under General Pollock, to be saddened immediately after by the death, in action, of his brother Alexander. A period of inactivity ensued, during which he was stationed at Meerut, doing duty as adjutant of his regiment. On the breaking out of the Sikh war in 1845, he served in the campaign on the Sutlej, and was present at the battle of Ferozeshah, though, as attached to the commissariat department, without special opportunity of distinguishing himself. After the cessation of the war, through the recommendation of Colonel (afterwards Sir Henry) Lawrence, N., now a

lieutenant, was appointed assistant to the resident at the conquered capital, Lahore, and thus fairly transferred to the political branch of the service, in which most of his future time was passed. But shortly, with the outbreak of the Sikh rebellion in 1848, there came an interlude of military activity, in which he greatly distinguished himself. To N.'s daring and promptitude was due the preservation to us of the important fortress of Attock; and soon after, his success at the Margulla Pass, in intercepting and defeating a large body of the insurgents, brought his name prominently before the world. Throughout the struggle which followed, he rendered important service; and at the great battles of Chillianwalla and Gujerat successively, he earned the special approval of Lord Gough, to whom he was immediately attached.

The Punjab having finally become a British province, Captain N. was appointed a deputy-commissioner under the Lahore Board, of which Sir Henry Lawrence was president. He had now been nearly ten years in India; his strength was somewhat shaken by arduous service, and various illnesses which from time to time had assailed him; and above all, he was anxious to visit and console his widowed mother, then prostrated by the death in India, by an accident, of William, his younger brother. In 1850, accordingly, he took his furlough, and returned home, taking Constantinople *en route*, and visiting, with an eye to professional instruction, the capitals of all the great military powers of the continent. On his return to India, he was again appointed by Lawrence a deputy-commissioner in the Punjab, and for five years subsequently his work lay among the savage tribes of the frontier. His success in bringing them under thorough subjection to law and order, was something marvellous; and such were the impressions of fear and reverence wrought by the force and massive personality of the man, that he became among these rude populations, under the title of 'Nikkul Seyn,' the object of a curious kind of hero-worship. So far was this carried, that a sect actually arose, of Nikkul-Seynees, who consecrated him as their Guru (or spiritual guide), and persisted—despite of severe floggings regularly inflicted by the worthy man, indisposed to accept of divine honours—in falling at his feet, and making him an object of express adoration.

With the outbreak of the great mutiny in 1857 came N.'s supreme opportunity, and the brief career of glorious achievements in which he developed in the eye of the world the full power and splendour of his military genius. In the saving of the Punjab, virtually India was saved to us; and under Sir John Lawrence, who had succeeded his brother, Sir Henry, N.—though not without noble coadjutors to divide with him the honour—perhaps did more than any other single man to hold firm our grasp of the Punjab. He it was who suggested the formation of the famous movable column, by which mainly the work was done, and presided over its organisation. Shortly, he was appointed to command it; and in his dealings with the suspected regiments of sepoyas, he exhibited a particular combination of boldness with subtlety, discretion, and astuteness, scarcely too much to be admired. At Trimmu Ghaut, on the 12th and 14th of July, he brought to bay, and nearly utterly annihilated, a large force of the declared rebels. Things thus made safe behind him, he marched to reinforce the army of General Wilson, engaged in the siege of Delhi, arriving in camp on August 7. His presence and counsels gave new impulse to the operations; and in every way he strove, with fiery and impatient energy, to expedite the delayed

assault. A strong body of the enemy having tried to make their way into the British rear, to N. was assigned the task of intercepting and bringing them to battle. This he achieved on August 24, near Nujffghur—under circumstances of extreme difficulty, in the most masterly manner surmounted—obtaining a most brilliant result in the complete ruin and dispersion of the mutineers. When the assault on the city was at last ordered, General N. (for to this rank he had now attained) was selected for the post of honour; and on the morning of September 14, he led the first column of attack. After the troops had forced their way into the city, an unforeseen check occurred, and N., ever in front, exposed himself in the most fearless manner to animate his men to advance. Conspicuous by his towering stature, he became the mark of the enemy's bullets, and fell, shot through the body. He lingered for some time in great suffering, and died on the morning of the 23d. Over the whole of India, the victory was saddened by his death; for it was felt that in John N., to use Lord Canning's expression, 'a tower of strength' had fallen. During the whole war of the mutiny, though it claimed many noble victims, there fell no man more regretted in his death than N., or in his death more worthy of regret. Throughout his career, he shone—as opportunity offered—a veritable 'king of men;' one of those born to command, who naturally and inevitably rise to it, and however great in achievement, seem to need only the hap of ampler opportunity in the future, to outsoar their great achievements in the past. No one ever seems to have come fairly in contact with him without being strangely impressed with this sense of a magnificent reserve of *power* in him. It remains only to add, that his nature was on the one side as gentle, tender, and affectionate, as on the other it was strong and brave; and that, by all who had intimate relations with him, he was not less beloved for his mild virtues, than for his sterner gifts honoured and admired. To his memory all honour was paid. The Queen commanded it to be officially announced that, had he lived, he would have been created a Knight Commander of the Bath; and by the East India Company, a special grant of £500 a year was voted to the mother who survived to mourn for him.—For further details of the life of this man of right noble and heroic mould, the reader is referred to the account of him—from which this little sketch is redacted—given in Mr Kaye's most interesting work entitled *Lives of Indian Officers* (2 vols., Lond. A. Strahan & Co., 1867).

NICOLAI, OTTO, a German musical composer of note, born at Königsberg in 1809. His early life was a struggle with poverty and difficulties. He studied for three years in Berlin under Klein; and in 1835 went to Rome, where he went through three more years of study under Baini. After travelling for ten or twelve years over Europe, he became, in 1847, Kapellmeister at Berlin, a post which he soon resigned. He appeared as a composer of dramatic music as early as 1831; but his first work of importance was *Il Templario*, founded on Scott's romance of *Ivanhoe*, which, produced at Turin in 1841, attained a high and permanent reputation. In 1848, he wrote at Berlin *Die Lustigen Weiber von Windsor*, on which his renown as a musician is founded, a work charming for its clear design and lively vigorous tone, whose overture is almost worthy of Weber. Two months after the production of this his *chef-d'œuvre*, its composer died at Berlin.

NICOSIA, a city of Sicily, in the province of Catania, 70 miles south-west from Messina. It is situated on the crest of a steep conical hill between

two head-branches of the Salso. It has scarcely any manufactures, but carries on some trade in corn, wine, oil, and cattle. Near it are beds of alum schist, a rich mine of rock-salt, and springs of petroleum. Pop. (1861) 14,251.

NIEUWER AMSTEL, a town of the Netherlands, in the province of North Holland, five miles south-by-west from Amsterdam. Pop. (1864) 7306. A few miles to the east of it is the village of Ouder Amstel, with about 3000 inhabitants, on the Amstel, one of the smaller mouths of the Rhine, which passes through the city of Amsterdam, and falls into the Zuider Zee.

NISCEMI, a town of Sicily, in the province of Caltanissetta, 10 miles north-east from Terranova, and on the right bank of the river Terranova. In 1790, this town was visited by an earthquake, and during seven shocks, the ground gradually sank, in one place to the depth of 30 feet. Fissures opened, which sent forth sulphur, petroleum, hot water, and mud. Pop. (1861) 9323.

NISCH, or NISSA, a town of Roumelia, European Turkey, 122 miles south-east from Belgrade. It stands on the left bank of the river Nissawa, a branch of the Morawa. The town is ill built; but many new houses, and a well-supplied bazaar, attest its present prosperity. N. has long been noted as the point of meeting of many roads, both of military and commercial importance. It seems likely to acquire fresh importance by the construction of a railway from Belgrade to Constantinople and Thessalonica. In ancient times, N. bore the name of *Naisos*, and was a flourishing town of Upper Mœsia. About a mile from it is a tower composed of human skulls, erected to commemorate a victory of the Turks over the Servians; and not far off is the hill of Woinik, or Kriegsberg, where, in 1689, the Markgraf Louis of Baden, with 17,000 men, destroyed a Turkish army of 40,000. Pop. 13,000.

NITI-GHAUT, a pass of the Himalaya, between the British district of Kumaon and Tibet. It takes its name from the village of Niti, in Kumaon, 13 miles south of the pass, in lat. 30° 47' N., and long. 79° 56' E. The pass is 16,814 feet above the level of the sea. This is regarded as the easiest pass between Kumaon and Tibet, and is consequently one of the principal channels of trade between Hindustan and Chinese Tartary. The Bhotias of Niti subsist chiefly by the carrying of goods in this trade. The articles of merchandise are conveyed on yaks, goats, and even sheep. Travellers often suffer much from difficulty of respiration on the pass of Niti-Ghaut, on account of the rarefaction of the air.

NITRO-BENZOL. This substance has recently taken a prominent place amongst the narcotic poisons. Under the name of *Essence of Mirbane*, it is largely employed, as a substitute, in perfumery and confectionery, for oil of bitter almonds, which it closely resembles in smell, and to confectionery it gives the smell, but not the agreeable taste of that oil. It is a pale, lemon-coloured liquid, with a pungent, disagreeable taste, and distinguishable by its odour from all other liquids, except oil of bitter almonds, from which it differs in the following reaction: Pour a few drops of each on a plate, and add a drop of strong sulphuric acid. The oil of almonds acquires a rich crimson colour with a yellow border, while the nitro-benzol produces no such colour. In 1859, Professor Casper of Berlin published an account of this liquid under the name of 'A New Poison,' and described its effects on dogs and rabbits. In 1862, and since that date, various cases of human poisoning have been published, both

in this country and abroad. We shall briefly notice three cases, in two of which the patient died, after swallowing a portion of the fluid; while in the other, the inhalation of the vapour proved fatal. A boy, aged 17, while drawing off some nitro-benzol by a siphon, swallowed a portion of the liquid. There were no immediate symptoms; but he soon felt sleepy, and when at dinner, ate but little, and said he felt as if he was drunk. This was between two and three hours after he had swallowed the liquid. He fell into a stupor, which became deeper and deeper, until death took place, without vomiting or convulsions, twelve hours after the ingestion of the poison. In the case of a man, aged 43, who spilled a quantity of nitro-benzol over his clothes, and went about for several hours breathing the vapour, the effects were nearly the same. The progress of each of these cases, both of which are described by Dr Letheby in the *Proceedings of the Royal Society* for 1863, was much the same as that of slow intoxication, excepting that the mind was perfectly clear until the coming on of the fatal stupor, which was sudden, as in a fit of apoplexy. From that moment, there was no return of consciousness or bodily power; the sufferer lay as in a deep sleep, and died without a struggle. The duration of each case was nearly the same, about four hours intervening between the swallowing or inhaling of the poison and the beginning of stupor or coma, which lasted five hours. Nitro-benzol, as well as aniline, into which it seems to have been partly converted in the body, was detected in the brain and stomach. It is unnecessary to describe the steps to be taken for the detection of the poison in all these cases: no one but a professed toxicologist should be intrusted with an investigation on the result of which the life and character of a human being may depend. It is satisfactory to read Dr Taylor's opinion, that 'there is no probability that this liquid will be successfully employed for the purposes of murder without the certainty of detection.'—*Principles and Practice of Medical Jurisprudence*, p. 311. It is worthy of notice that the vapour of this substance, as it is evolved from almond glycerine soap, has seriously affected females; and Dr Taylor mentions the case of a gentleman who, from using a cake of the soap in taking a warm bath, fainted from the effects of the vapour, and was ill for some months afterwards. The mode of treatment that should be adopted in poisoning by this substance, is essentially the same as that which should be adopted in poisoning by opium.

NITRO-GLYCERINE [$C_6H_5N_3O_9$], or $C_6H_5(NO_2)_3O_3$, known also as *Glonoin* or *Glonoin Oil*, is a compound which is produced by the action of a mixture of strong nitric and sulphuric acids on glycerine at low temperatures. Two methods of preparing it are given in *Watts's Dictionary of Chemistry*, vol. ii. pp. 890, 891, to which we must refer the reader who seeks for details on this subject. According to whatever method it is prepared, it is obtained as a light yellow oily liquid, of specific gravity varying from 1.525 to 1.6, inodorous, but having a sweet pungent aromatic taste; a single drop, however, if placed on the back of the tongue, produces headache and pain in the back, which last for many hours. It is only slightly soluble in water, but dissolves readily in ether, alcohol, and methylated spirits; according to Adriani (the *Chemical News* for January 3, 1868), it does not inflame or explode when touched by a light; but regarding its inflammability there seems a difference of opinion, for Richter of Freiberg, in a recent Memoir, entitled *Experiments with Nitro-glycerine*, observes that it does not take fire easily, and when

lighted, burns, but does not explode, and goes out as soon as the flame with which it has been brought in contact is taken away. On this very important point, further experiments are required. But although contact with flame does not cause it to explode, this result follows if it is exposed to a moderately strong blow or concussion, to the concussion due to the explosion of gunpowder, to contact with red-hot iron, and especially to the action of detonating mixtures and fulminates; it likewise explodes on exposure to a high temperature (see below); the explosion, however it is produced, being in all cases excessively rapid, and unaccompanied by smoke. It is this explosive power that renders this compound a useful agent in blasting. According to Dr Rudolf Wagner, the distinguished Bavarian technologist, it may be cooled down to 4° without becoming solid; but this statement probably refers to the chemically pure compound; for the nitro-glycerine of commerce, which has been patented by a German, under the name of *Nobel's Patent Blasting Oil*, becomes solid if exposed for a considerable time to a temperature of 46°, crystallising in long needles, which are most dangerous to handle, since they explode, even on being gently broken, with appalling violence. At 320°, nitro-glycerine begins (according to Dr Adriani) to decompose, giving off red vapours; and if the heat be suddenly applied, or slightly raised above this point, the substance explodes with great violence; while, according to other observers, it is liable to explode at 240°, or a little higher; and if exposed for a length of time to half that temperature, explosion may take place at 180° or less. It is obvious from the formula for nitro-glycerine that it may be assumed to consist of glycerine, $C_6H_5O_3$, in which three atoms of hydrogen are replaced by three of peroxide of nitrogen, NO_2 . The products of the complete combustion of 100 parts of pure nitro-glycerine are—water, 20 parts; carbonic acid, 58; oxygen, 3.5; and nitrogen, 18.5; and hence, it has been calculated that one volume (say, a cubic inch) of this compound, at a specific gravity of 1.6, yields, on combustion or explosion:

| | |
|-----------------|---------------------------------|
| Aqueous vapour, | 554 volumes (say, cubic inches) |
| Carbonic acid, | 469 " " |
| Oxygen, | 39 " " |
| Nitrogen, | 236 " " |
| | 1298 " " |

According to Nobel, these gases expand, on explosion, to 8 times their bulk; in which case, 1 cubic measure (say, 1 cubic inch) of nitro-glycerine will yield 10,384 cubic measures (say, cubic inches) of gases; while 1 cubic measure of gunpowder will only yield 800 cubic measures of gases. Hence, it follows that, for equal bulks, nitro-glycerine is 13 times as strong as gunpowder, while for equal weights it is 8 times as strong.

The danger of using this compound in mining, &c. is greatly increased by its instability. Even when pure, it is liable, at a heat of 70° or less, to undergo slow, spontaneous decomposition into glycerine, oxalic and hydrocyanic acids, ammonia, &c., with a continuous escape of gaseous products, which, exerting pressure on the liquid, renders it so prone to explosion that even a slight concussion is attended with danger; and the impure commercial compound decomposes far more rapidly than the pure nitro-glycerine: indeed, impure nitro-glycerine may, from this cause, be regarded as 'dangerously self-explosive even while standing quietly' (Adriani, *op. cit.*).

Many of our readers doubtless recollect the history of a terrific explosion that took place on board the ship *European*, when lying in harbour at Colon, Panama, on the 3d of April 1866. Amongst the cargo put on board at Liverpool were 70 cases of nitro-glycerine, and one case containing 70,000

NITRO-GLYCERINE.

percussion-caps. At 7 A.M. on the 3d, a most tremendous explosion occurred in the after-part of the ship. It was described as most rapid, without smoke, but with a great flame, and the ship was immediately after seen to be on fire. The whole of the deck and cabin aft were carried away, and the side of the ship was also much damaged, the plates above the water-line being blown away, and the parts below it being much injured. For fear of further explosions, the ship was towed into the bay, where she shortly sunk. Nor was the injury confined to the *European*; the jetty was nearly blown away, and a vessel lying on the other side of it was much damaged. Houses in the town were also partially destroyed, the floors in many cases being torn up; and altogether about 50 lives were lost. When the bodies were recovered, they presented no sign of smoke nor any symptoms of scalding; and hence it was inferred that the explosion could not have been produced either by the percussion-caps or by steam. On these and other grounds, the conclusion was irresistible that the explosion was due to the nitro-glycerine. An action was (August 1867) brought at Liverpool by the owners of the *European* against the shippers of the nitro-glycerine, on the ground that no due notice of the dangerous properties of that compound had been given; and at this trial, several of the important points regarding the explosive properties of nitro-glycerine, which we have noticed, were elicited from Professor Abel, chemist to the laboratory at Woolwich; Colonel Boxer, superintendent of the Woolwich Laboratory; and Professor Roscoe, who appeared as scientific witnesses. To give some definite idea of the explosive force of this substance, Professor Roscoe stated that one case of it would have sufficed for the destruction of the *European*. It is used to a considerable extent in the slate-quarries in Wales, and in mining operations. A workman at one of those quarries described how he had been set to clean a wagon which had held some of it, which he did by scraping it with a piece of slate; and inadvertently throwing the piece of slate into the wagon when he had finished, the percussion exploded the remnants of the oil, and the wagon was blown to pieces. He states that it is regarded as ten times as powerful an explosive agent as gunpowder.

We learn from a recent number of the *Nevada Gazette* (quoted in the *Chemical News*, August 16, 1867), that this substance is being advantageously employed in the blasting necessary for the construction of the summit tunnel on the Central Pacific Railway. The operation is said to be going on 25 per cent. faster than if powder had been used. The small holes required for the oil can probably be drilled in less than one-third the time required for the larger ones necessary in using powder. The oil does much more execution than powder, as it always breaks the rock from two to sixteen inches beyond the hole, and also throws out a much larger body. The oil is here estimated as having, in hard rock, a strength five times greater than powder. It is made upon the spot, and is considered much stronger as well as safer than the imported compound. It has been now used for several months, and there has never been any accident, nor has a single blast missed fire since the Chinamen commenced filling the cartridges. Colonel Schaffner of the United States army has published an official Report on this compound, to which he gives the name of 'nitro-leum,' which confirms the fact that its explosive properties are far greater than those of gunpowder. From a Report on the same subject by Captain Grant, R.N., it appears that it is exploded by percussion, and apparently, under ordinary circum-

stances, by nothing else—neither by friction nor fire. Generally, a trifling blow is sufficient to explode it. Its explosive force is about ten times that of gunpowder. It has all the appearance of common oil, and is usually carried in tin cases, each of which holds 25 lbs. Each can is packed in a wooden case for carriage. In a paper on this subject by M. Kopp, that chemist holds the view already noticed, that accidents are mainly due to the presence of impurities. He states that, by means of charges of 1500 or 2000 grammes of oil, from 40 to 80 cubic metres of a hard rock may be detached.

We have already noticed Richter's observations on the slight inflammability of this compound; and as the employment of this explosive agent seems to be increasing, we shall give his other chief results, so as to bring up our knowledge to the latest possible date. The shaft in which the experiments were made was being sunk 30 feet long by 8 feet wide, in hard gray gneiss with occasional joints, which facilitated the working. From these experiments, it appeared not only that its power was four or five times greater than that of the nitrate-of-soda gunpowder commonly used for mining purposes in Germany, but that other advantages accrued from its use, which may be summed up as follows: (1.) Fewer men are wanted for working out a certain-sized piece of ground, and fewer holes have to be bored than at present. (2.) Nitro-glycerine does not take fire easily (see above). (3.) The amount of smoke after a blast is small, as compared with that of powder; and workmen can return at once to the spot when the blast has taken place. (4.) Holes that have missed, or only partly torn, can be retamped and shot off, which, with the present arrangements, is impossible, or very dangerous. Against these advantages must be set off the following disadvantages: (1.) The gases formed during the explosion of nitro-glycerine have an injurious effect on the organs of sight and respiration. (2.) Nitro-glycerine explodes on being struck smartly, and easily freezes. (3.) The masses of rock which it removes are mostly very large, and considerable time has to be spent in breaking them up.

In another set of experiments, the relative cost of blasting by nitro-glycerine and gunpowder was compared, and it was found that a cubic fathom of ground could be removed by the former for £4, 0s. 4d.; the cost amounted to £5, 0s. 8½d. when the latter was used. In sinking a shaft in clay-slate by means of nitro-glycerine, the cost was under £3 per cubic fathom. For further details regarding these experiments, the reader is referred to the *Chemical News*, November 15, 1867, which contains a translation of Richter's valuable Memoir.

In the *Times* for December 10, 1867, there was a notice of a serious explosion from the employment of this agent within a few miles of the city of New York. The accident happened in the Berger quarries. Nine persons were blown to pieces, and ten or fifteen wounded, while the ground was shaken for fully a mile round, and several houses were destroyed.

The latest accident on record took place on Tuesday, December 17, 1867, at Newcastle, and occasioned the loss of seven lives. The editor of the *Chemical News*, December 20, 1867, remarks, that 'unless means are taken by the manufacturers to prevent explosions causing such lamentable results as these, a valuable blasting agent will be lost to miners and quarriers. If this be the case, however, the manufacturers of it will have themselves to blame, for explosions of nitro-glycerine during transport or storage ought to be unknown. It has recently been discovered that

nitro-glycerine dissolved in two or three times its bulk of methylated spirit is quite explosive, and that, when required for use, the addition of water will precipitate the oil, the layer of water and spirit merely requiring decanting off. The nitro-glycerine separated in this way possesses explosive properties quite as active as the original oil, which, indeed, is frequently rather improved than otherwise by the treatment. The process we have described is sometimes used. At Newcastle, a part of one canister was found after the explosion, marked "safety solution of nitro-glycerine in wood naphtha." It is, however, quite certain that there must have been a quantity of oil present, either entirely untreated, or treated with an insufficient quantity of the protecting fluid. It should be remembered that nitro-glycerine, dissolved in a small quantity of methylated spirit, or of wood naphtha in warm weather, might crystallise out in winter when the temperature approaches the freezing point of water. Probably this is what occurred. Shipping agents and railway companies should refuse to receive nitro-glycerine unless protected in the manner already indicated.

It will be observed that all these terrible accidents are of recent date. Although nitro-glycerine was discovered about 20 years ago by Dr Sobrero (now professor at Turin), it remained simply an object of scientific interest, till glycerine was manufactured on a large scale, that is to say, till eight or ten years ago. We believe that it was at the close of the year 1864 that it first became an article of commerce.

NOCTULE (*Vespertilio noctula*), the largest British species of Bat (q. v.), being nearly three inches long without the tail, which is fully an inch and a half. The ears are oval-triangular, shorter than the head; the muzzle is short and blunt. The N. is only seen on the wing during a short part of the year, retiring early in autumn to hollow trees, caves, or under the eaves of buildings, where many are sometimes found together.

NOMBRE DE DI'OS, a town of Mexico, 35 miles south-east from Durango, in a mountainous district. Near it are rich silver mines. Pop. 7000.

NORDEN, a town of Prussia, formerly of Hanover, in East Friesland, 72 miles north-west from Oldenburg, and a few miles from the North Sea, with which it is connected by a canal. Pop. (1864) 6119.

NORTHERN LIGHT-HOUSES, COMMISSIONERS OF, the body corporate which has under its management the whole of the light-houses of Scotland and Isle of Man. The body was first constituted by act of parliament 26 Geo. III., but has been frequently since the subject of legislation. The light-houses of the Isle of Man were assigned to it in 1815. By the Merchant Shipping Act, 1854, the Commissioners are so far limited in their powers, that any proposal for a new light-house must receive the approval of the Trinity House, London, and the outlay must be sanctioned by the Board of Trade; the cost, however, is borne by the imperial light-house fund. The Commissioners act wholly in virtue of office, and give their services gratuitously. The body consists of the Lord Advocate, Solicitor-general, Lord Provost and senior Bailie of Edinburgh; Lord Provost and senior Bailie of Glasgow; Lord Provost of Aberdeen; provosts of Inverness, Campbeltown, Dundee, and Greenock; the sheriffs of the following counties—Aberdeen, Argyle, Ayr, Berwick, Bute, Caithness and Sutherland, Edinburgh, Elgin, Fife, Forfar, Haddington, Inverness, Kincardine, Lanark, Orkney and Shetland, Renfrew, Ross, Wigtown, and Kirkcudbright. The

business of the Commissioners is conducted at an office in Edinburgh, with the assistance of a secretary and consulting engineers. In 1867, the number of light-houses under charge of the commission was 56, besides buoys and beacons. The Commissioners own a steam-vessel, the *Pharos*, for supplying stores to the several light-houses, and performing annual visits of inspection. The whole system of northern lights is remarkably well organised, the merit of which is in a great measure due to the late Robert Stevenson (q. v.). A Royal Commission appointed some years ago to inquire into the management of the English, Irish, and Scottish light-houses, has acknowledged that the 'Scotch light-houses are in the best state of general efficiency, the English next, and the Irish third.'

NOSSI-BÉ, NOSSI-BARIN, VARIOU-BÉ, or HELLEVILLE, an island on the north-west coast of Madagascar, at the mouth of the Bay of Pasoadava, and separated from the mainland by a narrow channel. It is about 74 sq. m. in extent; its coast-line is very much indented; and its surface much diversified. The highest hill is 1700 feet in height, and is clothed to the summit with magnificent trees; but much of the island has a bare aspect, the forests having been cut down in order to the cultivation of rice. The soil is very fertile, and rice, maize, manioc, bananas, &c., are produced far beyond the wants of the inhabitants. The soil is volcanic, and there are several old craters filled with water. Nossi-Bé has been in the hands of the French since 1840, and is regarded by them as an important possession, on account of an old claim which they suppose themselves to have to Madagascar. There is on this island a small town called Helleville, with a harbour well sheltered from the north and east winds. There is good anchorage also at several other parts of the coast. The pop. of the island is about 6000.

NOSSI-IBRAHIM, or SAINTE MARIE, an island on the east coast of Madagascar, and separated from it by a strait of about 5 miles in width. It is about 40 miles in length from north-north-east to south-south-west, but only a few miles in breadth. It is one of the much-prized possessions of the French on the coast of Madagascar, has been in their hands since 1750, and is their chief place of commerce on that coast. The soil is generally arid, and the climate moist and unhealthy. Rain is of extreme frequency. The pop. of the island is about 5000. It contains a small town called Saint Louis—a seaport, and fortified. All the French possessions on the coast of Madagascar were placed by an imperial decree of 1851 under one government, that of the Comoro Isles (q. v.).

NOTORNIS, a genus of birds of the family *Rallidae*, nearly allied to the coots, although in some of its characters it resembles the Ostrich family. One species only is known, *N. Mantelli*, a native of New Zealand. It is particularly interesting, because the genus was originally established and the species characterised by Owen, from remains found along with those of *Dinornis* and other large birds of the Ostrich family, called Moas by the New Zealanders. The bird was, however, ascertained in 1850 still to exist. It inhabits some of the most unfrequented parts of the Middle Island. It is larger than the other coots, but small in comparison with the true moas. The flesh is said to be delicious. It seems to be a bird likely soon to become extinct unless preserved by human care, and of which the domestication would be easy and desirable.

NOVELDA, a town of Spain, in the province of Alicante, and 18 miles west from Alicante, on the railway between Madrid and Alicante. There are

corn and oil mills, brandy distilleries, and manufactures of lace. Pop. 8095.

NOVELLO, CLARA, a distinguished vocalist, daughter of the following, was born in 1818. Her talent shewed itself very early. At the age of ten, she became a pupil of the French Academy of Singing for Church-music, and studied in Paris for several years, following up her studies in after-years in Italy and Germany. Both in England and in Italy, she created quite a *furor* from the year 1840 to 1848; her singing has indeed hardly ever been equalled in equality, flexibility, and executive skill. In 1848, she married Count Gligliucci, and quitted the stage, returning to it, however, for a time from 1850 to 1854.

NOVELLO, VINCENT, an eminent musical performer and composer, was born in London, of an Italian father and English mother, in 1781. At the age of 16, he was organist in the chapel of the Portuguese embassy; and even then had attained a large measure of that proficiency on the organ for which he was celebrated in later life. He was one of the founders of the Philharmonic Society. His musical compositions, which are very numerous, and chiefly sacred, are considered to have contributed much to the improvement of cathedral music. As a painstaking editor of unpublished works of eminent musicians, he has also done great service to musical literature. He died at Nice in 1861.

NOVGOROD-SSJEWERSK, or **NOVGOROD-SEVERSKOIE**, a town of Russia, in the province of Tchernigov, 89 miles north-east from Tchernigov, on the right bank of the Desna, a branch of the Dnieper. It is the capital of a district, and is a place of considerable trade and activity. Pop. (1863) 7142.

NOVGRAD-VOLYNSKI, a town of European Russia, in the government of Volhynia, 52 miles west-north-west from Jitomir. It is the capital of a circle, and is situated on the banks of the Slutch, a feeder of the Pripet, and so of the Dnieper. Pop. (1863) 7970.

NOWANAGA'R, or **NOWANUGGUR**, a seaport of India, in the peninsula of Kattywar, Guzerat, at the mouth of the Nagna, a small river on the south shore of the Gulf of Cutch, 160 miles west-south-west from Ahmedabad, and in N. lat. 22° 28', E. long. 70° 11'. It is the principal place of the district of Hallar, the greater part of which is held as a *jaghire* by the chief of N., who bears the title of the Jam of Nowanagar. His territory comprises 540 villages, and a pop. of about 210,000. The town of N. is large and populous, nearly four miles in circuit. It is a place of very active trade, famous for the fine quality of the cloth which it

produces, and for the brilliant colours of which its fabrics are dyed. In the adjacent sea are beds of pearl-oysters. Copper ore has been discovered in a range of hills behind the town.

NU'CHA, or **NUKHA**, a town of Russia; after Tiflis and Shemacha, the most important town of Transcaucasia, and the only town of the former khanat of N. or Sheki, in the north-west of Shirwan. It is 120 miles east-south-east from Tiflis, and stands at the southern base of Caucasus in the valley of the Kiah-Tahai, an affluent of the Alasan, which itself is a branch of the Kur. The town is surrounded by mulberry-groves and fruit-gardens, extending to a distance of several miles. It has long been famous for the rearing of silk-worms, silk-spinning, and the manufacture of silken goods.

NUGGI'NA, a town of British India, in the district of Bijnur, division of Rohilcund, North-west Provinces. It is 48 miles north-north-west from Moradabad, on the route from Moradabad to Hurdwar. N. is the Birmingham of Upper India, and is famous in modern times for the manufacture not only of gun-barrels but of percussion-locks. Pop. variously estimated from 14,000 to 30,000.

NULLIFICATION, in American politics, the doctrine of the extreme states' rights party, of the right of a state to declare a law of Congress unconstitutional and void, and if the Federal government attempted to enforce it, to withdraw from the Union. In 1832, during the presidency of General Jackson (q. v.), the free trade and states' rights party in South Carolina (q. v.), under the leadership of John C. Calhoun (q. v.), her senator in Congress, asserted the doctrine of Nullification in a state convention which declared the tariff acts of that year unconstitutional, and therefore null and void; that the duties should not be paid; and that any attempt on the part of the general government to enforce their payment, would cause the withdrawal of South Carolina from the Union, and the establishment of an independent government. President Jackson met this declaration with a vigorous proclamation, in which he declared that the laws must be executed, and that 'the Union must and shall be preserved.' South Carolina, standing alone, receded from her position under protest, and a 'Compromise Bill,' introduced by Henry Clay (q. v.) in 1833, providing for a gradual reduction of duties, for the time settled the controversy.

NYIREGYHA'ZA, a town of Hungary, in the county of Szabolcs, on the railway between Debreczin and Tokay. The trade in agricultural produce is considerable. N. has salt, soda, and saltpetre works. There are mineral springs in the neighbourhood. Pop. 17,487.

OEDENBURG, a town of Rhenish Prussia, 15 miles west-south-west from Düsseldorf, near the right bank of the Niers. It has manufactures of velvets, paper, leather, &c., and like many of the other manufacturing towns in the same district, has recently much increased in size and population. Pop. (1864) 7354.

OEDENBURG (Hung. *Soronyi*; anc. *Sempronium*), a town of Hungary, the capital of a county of the same name, is situated in an extensive

plain, about two miles west from the Neusiedler See, on the Ilkva, a branch of the Raab. It is connected by railway with Vienna. O. is one of the most beautiful towns in Hungary. It has manufactures of cotton and woollen goods, potash, nitre, tobacco, sugar, earthenware, glass, cutlery, &c.; and a considerable trade in wine, corn, tobacco, wax, honey, and cattle, the products of the neighbourhood, which is rich and well cultivated. The wine of Rust, a small town eight miles north of O., on hills sloping to the Neusiedler See, is one of the best wines of Hungary, and inferior only to

Tokay. The Roman station of *Sempronium* was one of considerable importance; and numerous Roman remains are found near Oedenburg. The inhabitants of O. are mostly of German race. Pop. 20,000.

OESEL, an island of Russia, in the Baltic, belonging to the government of Livonia, and lying across the mouth of the Gulf of Riga. It is about 80 miles in length from north-east to south-west, and about 40 miles in greatest breadth, but the south-western end consists of a comparatively narrow peninsula. A narrow strait separates the north-eastern end from the island of Dago. The surface is undulating, broken by low hills, marshy, watered by numerous small streams, and well wooded. The coast is generally formed by high cliffs. The climate is milder than that of the neighbouring continental districts. The rocks are generally calcareous, and the soil is in many places gravelly; the chief crops are wheat, oats, rye, barley, and peas. The rearing of cattle, horses, and sheep, and fishing, are, however, the principal occupations of the inhabitants. The seal-fisheries are of some importance. Pop. 46,000, mostly Lutheran. The only town is Arensburg, on the south-east coast, with a pop. (1863) of 3378. Many of the inhabitants of Arensburg are of German descent, as are the nobles and clergy of the island; but the peasantry are Esthonian. The islanders of O. were in early times noted as pirates. The Danish king Waldemar conquered the island in the beginning of the 13th century. Albert von Buxhöden, Bishop of Leal in Livonia, obtained it from Denmark in 1227, in order that he might reduce its inhabitants to subjection, and convert them to Christianity. Being partly subdued by the Teutonic Knights, it remained for more than 300 years under its bishops, the seat of the bishopric being transferred to the island. The last bishop sold it to Denmark in 1559. It remained a Danish province till 1645, when it was given up to Sweden, and in 1721, fell into the hands of Russia.

O'FFA'S DYKE, a remarkable relic of antiquity, an entrenchment extending along the whole border of England and Wales, from the north coast of Flintshire, on the estuary of the Dee, through the counties of Denbigh, Montgomery, Salop, Radnor, and Hereford, into Gloucestershire, where its southern termination is near the mouth of the Wye, in the grounds of Sedbury Park, which overlook the estuary of the Severn. In some places, it is nearly obliterated by cultivation; in others, it is of considerable height, although its appearance nowhere indicates that it can ever have been of much value as a rampart. It is therefore generally supposed to have been chiefly intended as a line of demarcation. Nearly parallel with it, but at a distance varying from a few hundred yards to three miles, on the eastern or English side of it, is *Wall's Dyke*, a similar relic of antiquity, which, however, seems never to have been so great a work, and is now in many places much obliterated. It has been conjectured that the space between them was neutral ground where the Anglo-Saxons and Welsh met for trading or other purposes. The principal dyke is ascribed by tradition to Offa, king of Mercia, who reigned in the 8th c.; but this is matter of tradition, and not of history.

OFFENBACH, JACQUES, a composer of dramatic music, who enjoys high popularity over the continent, of German birth, but a naturalised Frenchman. He was born in 1819, became *chef d'orchestre* in the Théâtre Français in Paris in 1847, and afterwards manager of the Théâtre des Bouffes-Parisiens. He has composed a vast number of light lively operettas, *Le Mariage aux Lanternes*, *La*

Fille d'Elezondo, &c., perfect as musical trifles; but the productions by which he is best known are a series of *bouffonneries musicales*, or burlesque operas, including *Orphée aux Enfers*, and *Geneviève de Brabant*, composed with the rather questionable aim of parodying music of a more serious description. The high public favour accorded to his works has, within the last two years, been extending to England.

O'GOBAI, a large river of Western Africa, which falls into the sea by many mouths, between S. lat. 0° 40' and 1° 20'. Its delta is very large, and forms a most complicated network of rivers, flowing amidst a dense forest. The most northern mouth of the O. has long been known as the river Nazareth, and falls into a bay of the Atlantic, on the north of Cape Lopez. Another principal mouth, to the south of that far-projecting cape, is known as the Mexian; and the southernmost, which seems to be the largest of all, is the river Fernand Vas. These were regarded as distinct and large rivers, till the explorations of Du Chaillu revealed their relation to each other, and to the main river Ogbai. The extent of the basin of the O., its sources, and the length of its course, are yet unknown, but it may be deemed certain that it is by far the largest river of Western Africa between the Niger and the Congo. For almost all our knowledge of the O., and the country through which it flows, we are indebted to Du Chaillu, although, in the interval between his first and second visits, the lower part of its course was partially explored by two French expeditions. Not far from its mouth, the Fernand Vas is joined by the Rembo, also a large river, although much inferior in size to the O., which, after flowing in a south-westerly course from the interior, bends northward, and pursues a course nearly parallel to the coast for about fifty miles, the narrow peninsula between the river and the sea being a sandy and grassy prairie, with scattered groups of fine trees, frequented by herds of the Niare (q. v. in SUPPLEMENT) or wild ox of Western Africa, and of antelopes. The dense forests of the O. are the main haunts of the Gorilla (q. v.), and of several other anthropoid apes, discovered by Du Chaillu, among which are the Nest-building Apes (q. v. in SUPPLEMENT). Prodigious flocks of marabouts also come to lay their eggs on these prairies, and in the wet season, numerous pools are formed, which teem with fish. The forest-regions produce few of the mammalia, herbivorous and carnivorous, so abundant in other parts of Africa; and even birds are few. About 150 miles from the mouth of the O., the main stream is formed by the junction of two rivers, the Okanda and the Ngouyai—the former, which is said to be the larger of the two, coming from the north-east; the latter, which alone was explored by Du Chaillu, from the south-east. This river, after a long course through the table-lands of the interior, bursts through the mountain-range which separates them from the level country of the coast; the possibility of navigation being here cut off by a magnificent fall, and still more magnificent rapid, in which the river rushes down a steep declivity through a rocky chasm. Both above and below the fall, however, it is quite suitable for navigation by steamers; but a great impediment to commerce, when commerce shall spring up in that region, will be found in the difficult bar at the mouth of the Fernand Vas. The rainfall on the upper parts of the O. is supposed to be very great. The observations of Speke and Burton on the eastern side of tropical Africa, and of Du Chaillu on the western, concur in shewing that this must be the case. Rainy and dry seasons alternate on both coasts, but as the traveller proceeds inland, rain becomes more

frequent, falling almost every day, and it would seem at all seasons alike.

OHLAU, OLAU, or OLAWA, a town of Prussian Silesia, 17 miles south-east from Breslau, on the right bank of the Ohlau, a branch of the Oder. O. is a station on the railway which connects Breslau and the north with Vienna. It is an ancient town, with a royal palace and an old castle. At the present day, it is a place of considerable industrial activity. Being the capital of a circle, it has numerous district courts and offices. Pop. (1864) 6942.

OIDIUM, an important genus of minute fungi of the section *Hyphomyces*, growing on diseased animal and vegetable substances. They consist of minute tubular threads, forming flocks, white in some species, brightly coloured in others, simple or irregularly branched, assuming in their upper part the form of strings of beads, which finally break up into elliptic spores. The species actually existing are probably much more numerous than those which have been fully ascertained. Among the most important of the vegetable parasites of man is *O. albicans*, which is found on the epithelium in the

Fig. 1.—Thrush Fungus (*Oidium albicans*): general view.

mouth and throat in the disease called *aphthæ*, or thrush, and on that of the throat in diphtheria, also sometimes in the nostrils, stomach, and intestines, on the nails, the nipples, and other places. It is more common in children and in aged persons, than in those who are in the prime of life. It occurs frequently in the last stages of many diseases, when the mucous membrane is covered with nitrogenous decomposable matter. Indeed, it would seem that whatever may be the case as to other vegetable parasites, no species of *O.* begins its attack upon a perfectly healthy surface, either animal or vegetable; a diseased state of the tissue being to these fungi a necessary condition of vegetation, 'just as the yeast-plant will not vegetate save in a fermentable fluid, that is, in a solution which, in addition to sugar, contains some decomposable albuminous matter.' *O. albicans* appears to the naked eye as a white pasty

Fig. 2.—Perfectly developed thallus threads, shewing constrictions, partition walls, and ramifications.

511

substance, slightly elevated above the mucous membrane to which it adheres; but under the microscope, its filamentous structure is easily perceived. Its seat is at first on the upper surface of the epithelial cells, but its filaments soon penetrate deeply between them, and the upper epithelial layers are soon worn out, and thrown off by the rapid growth from below. However incapable the *O. albicans* may be of attacking a healthy surface, there can be no doubt that it greatly contributes to the extension of disease, and that it is very readily communicated from one patient to another when there is catarrh or other inflammatory affection of the mucous membrane.

Fig. 3.—Ends of perfectly developed thallus threads, more highly magnified (460 diameters).

Another species of *O.* which has recently attracted great attention, is *O. Tuckeri*, regarded by many as producing the grape disease, of late so injurious in the vineyards of many parts of the world, but in accordance with the views already expressed, perhaps rather to be regarded as merely accompanying and extending the disease. It may probably be the case that over-cultivation of particular varieties of grape, and too long continued cultivation on the same ground, have so impaired the vigour and healthfulness of the plants, as to make them liable to the attacks of this parasite. *O. Tuckeri* makes its appearance at first in the form of a mycelium of webby, creeping, branching filaments (fig. 4, b), which send out upright or decumbent jointed stems (fig. 4, a). The bead-like joints of the stems become successively filled with spores, which are finally discharged in little clouds for the multiplication of the species. The grape disease was first observed in Kent, England, in the spring of 1845, on vines in the vinery of Mr Tucker. The ends of the young shoots assumed a crispy appearance, began to wither, and then dried up. The unripe grapes were next attacked, becoming covered with a grayish-white bloom, the skin of the grapes being destroyed, and they rotted and dried up. The disease rapidly spread over other English vineries;

was observed about the same time in the vineries of Paris, and soon in the vineyards of almost all parts of France, Italy, Greece, Tyrol, and Hungary; finally, and in a slighter degree, affecting the vineyards of the Rhine. Its ravages extended to Algeria, Syria, Asia-Minor, and many other countries, among which is particularly to be noticed the island of Madeira, where it proved almost completely destructive to the grapes, and nearly put an end to the production of the celebrated Madeira wine. The importation of Madeira wine to Britain in 1831 amounted to 209,127 gallons; and in 1861, only to 28,749 gallons. It is probable that the complete

Fig. 4.—Grape Fungus (*Oidium Tuckeri*): early stage.

678

isolation of the Madeira vineyards made the progress of the disease more rapid, and its results more complete than elsewhere, by causing a prevalence of the conditions favourable for it. No kind of vine escaped. The grape disease is first perceived in the leaves, which become whitish, in consequence of a mycelium spreading over the upper surface of the leaf. The leaves sometimes curl up, or they become black at the centre, the blackness extending towards the circumference, and finally they drop off. The plant, through loss of its leaves, now becomes more unhealthy; the shoots are attacked by the disease, the stalks of the bunches of grapes, and the grapes themselves. The parasite penetrates into the young wood, the shoots are covered with spots and blotches of a reddish brown, or even black colour, and look as if a red-hot iron had been applied to them. Sometimes they secrete a clammy inodorous fluid all over their surface; and in many cases they wither from the top down half their length. The affected grapes very often first exhibit the disease in a single whitish spot on a single grape of a bunch, which enlarges by radiating irregularly. Fig. 5 represents a fragment of a grape with mycelium and erect fertile filaments. If in a bunch

Fig. 5.—Fragment of surface of Grape, with oidium fully developed.

there is one abortive grape, it often shews signs of the disease, whilst the rest remain free. The creeping branches of the mycelium are fixed upon the skin of the grape by rootlets, which do not penetrate into the juicy pulp. The mycelium sends up vertical fertile branches of nearly equal height, densely aggregated, and forming a velvet-like mass. The extremities of these become beaded; and at last the uppermost cell or bead increases in volume, becomes detached, and is carried off by some slight breath of air, to multiply the species by the dispersion of its spores. The other bead-like cells follow in succession.

Various means have been resorted to for the prevention and cure of the grape disease. The application of pulverised sulphur has been found useful, the fungus withering and drying up when brought into contact with a minute particle of sulphur. The application of sulphur must be frequent, as portions of the mycelium and some of the spores always escape. The use of sulphur has been the chief means of checking the spread of O. in French and other European vineyards; it is now general in the south of France and in Italy; and in consequence of its national importance, the duty on sulphur has been reduced by the French government. Hydrosulphide of lime has also been applied to vines with very beneficial effect. It is prepared by thoroughly mixing 68 ounces of flowers of sulphur with the same quantity of slaked lime,

adding three or four quarts of water, boiling for about ten minutes, allowing it to settle, and decanting the clear liquor. When it is to be used, one quart is mixed with 100 quarts of water, and it is poured over the vines.

OIL-FUEL. A great incentive has been given by the discovery of copious wells of petroleum (see **OIL-WELLS AND OIL-TRADE**) to the invention of some mode of using oil as a fuel for furnaces and stoves. Such attempts had often been made before; but they assume a new aspect now that oil has become so much cheapened. Nearly half the carrying capacity of European steam-ships, and more than half in those which make long voyages, is taken up with the stowage of coal. Petroleum (q. v.), if wholly burned, and all the heat utilised, gives out much more heat than an equal weight of anthracite or steam coal.

Mr Richardson made some experiments for the government at Woolwich in 1866. His grate consisted of two iron boxes, one within the other; the inner contained oil, and the space between the two boxes contained water. When the water boiled by the application of heat, and the oil began to arise in vapour, a jet of steam was admitted to mix with the vapour. The steam was found to assist the perfect combustion, so as to avoid the production of smoke. One object was, to ascertain whether the refuse of the stills, resulting from the distillation of shale oil, could be made available as furnace-fuel. The government published a Report of the Experiments, with diagrams, in 1866. It was considered that petroleum, used instead of coal as fuel, (1) raises steam more rapidly; (2) requires a smaller furnace and boiler; (3) maintains a more continuous fire and heat; (4) affords means of varying the intensity of the fire more quickly; (5) is extinguished instantly by turning off the oil and keeping on the steam; (6) produces no smoke, ash, or dust; (7) dispenses with some of the staff of coalers and stokers; (8) economises space for coal-bunkers; (9) reduces the dead-weight carried by the ship; (10) occasions no loss of heat by opening furnace-doors; (11) keeps the engine-room clean and comparatively cool; and (12) admits of the furnace-fires being lighted much more quickly. A modified form of oil-furnace was tried at Woolwich by Mr Richardson in 1867, not only with refined petroleum, but with the same oil in its crude form, shale-oil, naphthaline, creosote, grease, and residuum tar.

Experiments have been conducted with the same object in America. Mr Isherwood, chief of the bureau of steam-engineering in the United States navy, conducted a series of experiments, in 1867, on Colonel Foote's furnace for burning petroleum, and fitted up the iron gunboat *Palos* for this purpose, under the direction of a board of engineering officers. Most of the advantages claimed for Richardson's apparatus seem to be equally applicable to this of Foote.

There is a petroleum furnace by Messrs Wise and Field, patented in 1867, in which the oil is injected into the furnace by the pressure of superheated steam. There are many other forms of oil-furnace by Hill, Stevens, Sim, Barff, the American Petroleum Light Company, &c.

Many of the advantages of oil-fuel already mentioned are pretty generally conceded; but the questions of *safety* and *cheapness* are not yet settled.

OIL-WELLS AND OIL-TRADE. One of the most remarkable trades, suddenly sprung up into importance in modern times, is that in oil obtained from subterranean sources. See **NAPHTHA**.

It is now known that oil-bearing mineral beds exist in various parts of America, as well as in the

older continent; but the richest deposit hitherto discovered is in the United States, in Venango county, at a spot in Pennsylvania not far from the point of junction of that state and New York state with Lake Erie. Oil had for many years been seen floating on the surface of the water of a well near Titusville; it was taken up by absorption by means of flannel, and applied to medicinal purposes. Dr Brewer, in 1853, suggested that it might possibly be used for lubricating and for illumination; and in the following year was formed the Pennsylvania Rock-oil Company. This Company languished until 1858, when Colonel Drake, manager of the Company, and Mr Bowditch, resolved to sink a well purposely for oil. They were amply rewarded, for oil was pumped up at a rate varying from 400 to 1000 gallons daily. The news being spread abroad, adventurers quickly came to the district, which obtained the names of Oil Creek and Petrolia; and they experienced every degree of fortune from utter failure to splendid success, according to the spot at which they happened to sink their wells. So rapidly did the works proceed, that by 1860, it was known that oil existed beneath 100 square miles of country, at a depth varying from 70 to 500 feet. In 1861, the first large *flowing* well was struck—that is, a well up which the oil rose so profusely as to flow over the surface, yielding 1000 barrels (of 40 gallons each) per day; and another that yielded 2500 barrels. This new good fortune increased the excitement and the well-digging.

The uncertainty in this trade is something extraordinary. On one occasion, a well was bored with the usual centrebit to a considerable depth without any oil being found. On withdrawing the bit, and putting in the rimer or rimmer to widen the hole, a vein was struck at the side. The bit had just missed the vein, and the well would have been a failure had not the orifice been enlarged. This incident gives meaning to a phrase much used in America—that of 'striking oil.' On another occasion, a well was bored which promised to be very productive, a large amount of oil flowing; the owner of the well not being ready to collect it, a plug was driven into the pipe; but upon the removal of this plug, when tanks had been built, the oil had altogether disappeared. The deepest well sunk in the district, more than 1000 feet, yielded no oil whatever; and altogether only 15 per cent. of the borings were successful. Very often, there was twice as much water as oil in the liquid pumped up; and in some instances, the mixed oil and water was suddenly succeeded by water alone, thereby putting a stop to any further profitable operations.

When the oil began to be sent in large quantity to New York and other towns, the cheapness of price led to its application as lamp-oil, as fuel to be converted into gas, and in many other ways: this led to a constantly increasing demand; the demand brought the price up again to a reasonable figure at Petrolia; and the price induced the sinking of new wells. Considering that the produce of the district reached 20,000,000 gallons in 1861, it can be easily understood that commercial arrangements multiplied rapidly. Small villages rose into large towns, with banks, hotels, and wealthy people, all, however, begrimed with oil. Titusville, which had 243 inhabitants in 1855, rose to nearly 10,000 in 1866. Another place, called Oil City, had its two newspapers devoted mainly to oil-news, and transacted business to the amount of £3,000,000 per annum. By the end of 1866, it was estimated that there had been 90,000,000 dollars invested altogether in this and other parts of the United States; and that the average price at the well's mouth had

settled down at about 10 dollars per barrel, or a shilling a gallon.

In July 1860, oil was discovered in the state of Ohio, and within six months, 50 wells were sunk there. At Sandy Valley in Kentucky, Perry County in Indiana, Gardiner in Illinois, Yates County in New York, and Chattanooga in Tennessee, the oil-wells have attracted some attention. The Canadian deposit is a remarkable one. Near a village, now a large town, called Oil Springs, in Inniaskillen County, at the southern end of Lake Huron, a busy community has sprung up. In 1857, while sinking a well at this spot, in a forest where much semi-solid tar-like matter had often been found, the men were surprised by a sudden upburst of oil. This discovery set enterprising adventurers to work; and by the year 1863 there had been more than 200 wells sunk, within an area of only two miles by one. At first, the oil flowed from most of these wells; but the level gradually sank, and the oil could only be obtained by pumping. At the end of the six years, one half of the wells had ceased altogether to flow; and the wells since dug have been still more uncertain in their yield. The oil appears to lie in fissures in the limestone; but the well-borers have not yet succeeded in finding symptoms whether a particular spot will yield profitably or not at all. One particular well gave 35,000 barrels in ten months, and by that time had exhausted itself. The recognised rental became, 700 dollars down per acre, and one-third of the oil. The oil requires refining, to remove the tar, the volatile constituents, and the offensive odour. The Canada oil appears to be more disagreeable than that of the United States, and to be less in favour in consequence.

The average produce per well in Pennsylvania and Canada cannot be stated, on account of the extreme fluctuations. In 1861, there was an estimate that 100 wells in Petrolia yielded 15 barrels per day each. Annual statistics set down the produce of all the United States oil-wells in successive years at the following quantities: 24,000,000 gallons in 1861, 40,000,000 in 1862, 70,000,000 in 1863, 87,000,000 in 1864, and 91,000,000 in 1865. The price at New York has ranged between the very wide limits of 9 to 55 cents per gallon for crude oil, and 19 to 120 cents for refined. The oil was first imported into Liverpool in 1861, since which year the import has steadily and greatly increased.

In 1865, a shale was discovered in New South Wales, similar to the Boghead coal or Torbanehill mineral of Scotland, but richer in oil, and more free from sulphur. When distilled at Sydney, from 100 to 160 gallons of oil were obtained from one ton of shale. The seam in Hartley district is 5½ feet thick. Efficient distilling apparatus has been sent out from England; and the shale is either distilled for oil or for gas, according to circumstances. See NAPHTHA.

OLHÃO, a town of Portugal, on the sea-coast, near Cape de St Maria, and five miles east from Faro. Pop. (1863) 7025.

OLÍANDA, a city of Brazil, in the province of Pernambuco, and four miles north-east from Pernambuco. It was formerly the capital of the province, and there were bloody contests between Spain and Holland for the possession of it. It is still a bishop's seat, Pernambuco being included in the diocese. The whole aspect of the town is that of a place half deserted. Pop. 8000.

OLIVENZA, a town of Spain, near the Portuguese frontier, 19 miles south-by-west from Badajoz, on a small river which flows into the Guadiana. The chief branches of industry are the expressing

of oil, weaving, and the making of earthenware. From the treaty for the cession of O. by Portugal to Spain in 1801, Godoy acquired his title of Prince of the Peace. Pop. 10,000.

OLOT, a town of Spain, in the province of Gerona, and 22 miles north-west from Gerona, near the base of the Pyrenees, on the Fluvia. There are 14 volcanic cones close to the town; the crater of the largest is a mile in circumference and 445 feet in depth. The whole district is volcanic. In many places, and even in the town itself, currents of air blow continually from the porous lava. These are called *Bufadores* and *Sopladores*, and some of them are conducted beneath houses, and used as refrigeratories in hot weather. They maintain the temperature of about 53° F. both in hot and cold weather, but the gust of air is strongest in hot weather. O. was almost destroyed by an earthquake in 1421, but was soon rebuilt. Pop. 12,070.

ONEGLIA, a town of North Italy, in the province of Porto Maurizio, on the Gulf of Genoa, 40 miles east-north-east from Nice, at the mouth of the Impero, a small river which rushes down from the Apennines. The harbour is not good. The principal article of export is oil. Andrea Doria, the great Genoese admiral, was born here. Pop. (1861) 7689.

ONTENIENTÉ, a town of Spain, in the province of Valencia, 45 miles south-by-west from Valencia, on the right bank of the Clariano, and near the railway which connects Valencia with Madrid. Linen and woollen fabrics are manufactured here; there are also numerous oil-mills. Pop. 9508.

OOMRAWUTTI, or AMRAWATI, an important commercial town of British India, in the district of Hyderabad, 86 miles west-by-south from Nagpore, on one of the head-waters of the Purna, a branch of the Tapti. The district which contains it was ceded by the Nizam to the British government; and transit-duties, which formerly much interfered with the commerce of the town, have been abolished. Several considerable business firms are established here; and the chief merchants of Upper India and of Bombay have agents, who often make advances to the cotton-cultivators of the surrounding country, on security of their crop. There are large cotton warehouses at Oomrawutti.

OOTRUM, an Indian fibre, derived from the stem of *Damia extensa*, a plant of the natural order *Asclepiadiaceae*, abundant in many parts of Hindustan. The fibre is soft, white, silky, and strong, and is regarded as a promising substitute for flax.

O'PPENHEIM, a town of the grand duchy of Hesse-Darmstadt, in the province of Rhenish Hesse, on the left bank of the Rhine, 10 miles south-by-east from Mayence, and on the railway between Mayence and Spire. It stands on the steep slope of a hill abounding in vineyards, and carries on a pretty active trade in wine. O. occupies the site of the Roman castle of Bauconia, and was made a royal palatinate under the Carlovingians. It afterwards became one of the most important free towns of the empire. It was taken in 1218 by Archbishop Adalbert of Mayence, in 1620 by the Spaniards, in 1631 by the Swedes under Gustavus Adolphus, and in 1634 by the imperialists, suffering much upon all these occasions. In 1689, the French under Melac almost entirely destroyed it. The church of St Catharine, a fine specimen of the German architecture of 1262—1317, a kind of miniature of the Cologne cathedral, lies yet in a ruinous condition, except the eastern part, which was restored in 1838—1843. Pop. (1864) 3010.

ORENSE (anc. *Aqua calida Ciliorum*, or *Aqua Originis*), a city of Spain, the capital of the province of Orense, in Galicia, near the frontier of Portugal, on the left bank of the Minho. O. contains a number of interesting ecclesiastical edifices. It is highly reputed for its hot sulphurous springs, called *Las Burgos*, which issue—three in number—almost boiling from a granite rock in the western part of the town. The baths of O. were known to the Romans, and were in much repute among the Goths. O. carries on manufactures of linen, leather, and chocolate. It has a large trade in hams, which are in great repute throughout Spain. Pop. (1860) 10,775.

OROSZHÁZA (pronounced *Oroszdaa*), a thriving town of Hungary, in the county of Békés Csanad, 31 miles north-east from Szegedin. Pop. 12,663.

ORURO, or, in the complete form of the name, *San Felipe de Asturia de Oruro*, a town of Bolivia, the capital of the dep. of Oruro. It is situated about nine miles east from Desaguadero, and 32 miles north from the northern extremity of the salt lake of Desaguadero, on an affluent of the river of the same name which falls into that lake. It is 12,015 feet above the level of the sea, at the base of a very high mountain; but on the other side of the town is a large plain, often covered with saline efflorescences. The soil of the whole department is saline, and far from being fertile, but its mineral wealth is great. Gold, silver, copper, tin, iron, lead, and antimony are among its products. O. was founded in 1590, in consequence of the discovery of silver mines, which proved more productive than any in Bolivia, except those of Potosi. It soon became a wealthy and flourishing city with 70,000 inhabitants; but in consequence of the diminished productiveness of its mines, and of the anarchy prevailing in the country after the Revolution, its population declined, and is now only 7980. It has recently been made the seat of the Bolivian government, and the place of meeting of congress.

O'SCHERSLEBEN, or GROSS-OSCHERSLEBEN, a town of Prussian Saxony, on the left bank of the Bode, a branch of the Saale, 22 miles west-south-west from Magdeburg. Pop. (1864) 7065.

OSTRICH-FARMING. Attempts are being made to increase the supply of ostrich feathers, or to facilitate the procuring of them, by establishing farms—enclosures where the birds can grow and breed in tameness. In 1859, the Bulletin of the Société d'Acclimatation contained a note from Dr Vavasseur, discussing the question whether the ostrich of South America, the Nandu (q. v.) or *Rhea*, can be acclimatised in France. When caught, they are easily tamed; and this is the circumstance which has suggested the idea of naturalisation. They must not be placed in cages, but must have free range to walk about, secured simply by a leg-guard. Dr Vavasseur expressed an opinion 'that the South American ostrich could live without difficulty in the north of France; that there is no difficulty in domesticating it; and that it will feed on almost anything that is given to it, however coarse.

At a meeting of the Cape Agricultural Society of Cape Town, in 1864, Mr L. von Maltitz gave an account of his experience in ostrich-farming at Colesberg. Towards the end of 1863, he purchased seventeen young ostriches of three or four months old, and placed them in an enclosure of 300 acres, over which they had free run. They subsisted wholly on the herbage of the enclosure, save a little grain given to them now and then. The

opinion he formed from many months' observation was, that 35 ostriches might find sufficient sustenance upon 300 acres of good grazing-ground. In April 1864, he had the wings of the birds cut at the point where the well-known ostrich feathers grow; and they were fit again to cut six months later. The birds were so tame that they allowed themselves to be handled, and their plumage minutely examined. Having caused the birds and the feathers to be examined by experienced dealers, he found that the largest feathers, of which there are twenty-four on the wing of each male bird, were worth £25 per lb.; and that one plucking of his seventeen birds would yield £10 each on an average. The probability was that the value would rise to £12 when the birds were older. The birds cost him about £5 each. The price at Cape Town, at the end of 1864, for ostrich feathers brought to market in the usual way, was £25 to £30 per lb. Mr Von Maltitz anticipated a high rate of profit from his ostrich-farming, and recommended the system for adoption among the farmers of Swellendam.

The suggestions in relation to the South American ostrich, and the actual proceedings in reference to the South African, are receiving attention in France, and also in Algeria. The director of the Jardin d'Acclimatation at Hamma, in Algeria, has succeeded in getting the birds to breed in the domestic state.

The egg of the ostrich, though coarse, is reasonably good food; but the naturalisation of the bird derives most of its prospective importance from the feathers, for which there is at all times a large demand in the chief European countries.

OSTUNI, a city of South Italy, in the province of Lecce, 22 miles west-north-west from Brindisi, on the railway between Ancona and Brindisi. It stands on a steep hill. A considerable trade is carried on, chiefly in the produce of the neighbourhood, and the city is a flourishing one. Pop. (1861) 15,392.

OTO'LITHUS, a genus of fishes of the family *Sciænidæ* (q. v.), having a perch-like form, a convex head, with cellular bones, feeble anal spines, no barbels, long curved teeth or *canines* among the other teeth. A valuable species of this genus is the WEAK-FISH, or SQUETEAGUE (*O. regalis*), which is common on the eastern coasts of North America, from the Gulf of Mexico to the Gulf of St Lawrence, and attains a length of two feet. It appears on the coasts only in the warmer part of the year. It swims in shoals near the surface, takes bait greedily, and may be readily taken by any soft bait. It enters the mouths of rivers where the water is brackish. The flesh is pleasant, but soon gets soft. Excellent isinglass is made of the air-bladder.—A number of species of *O.* are found in the East Indian seas, some of which are valuable for the isinglass which is made from their air-bladder, and some are much used as food, both fresh and dried.

OTTO (or ATTAR) OF ROSES is the volatile oil or otto (see PERFUMERY) of the petals of some species of rose, obtained by distillation, and highly prized as a perfume. It is a nearly colourless or light yellow crystalline solid, at temperatures below 80° F., liquefying a little above that temperature. It is imported from the East, where in Syria, Persia, India, and Turkey, roses are cultivated to a considerable extent for its sake. It is probable that the oriental otto is the produce of more than one species of rose; and it is uncertain what species is cultivated in some of the localities most celebrated for it; but *Rosa Damascena* is known to be so employed in the north of India, and a kind of otto is sometimes obtained by the makers of rose-water

from *Rosa centifolia* in England. See ROSE. Ghazipore, near Benares, is celebrated for its rose-gardens, which surround the town, and are in reality fields occupied by rows of low rose-bushes, which in the flowering season are red with blossoms in the morning, but the blossoms are all gathered before midday. Cashmere is noted for its extensive manufacture of otto, as are also the neighbourhoods of Shiraz and Damascus. To procure the otto, the rose-petals are usually distilled with about twice their weight of water, and the produce exposed to the cool night-air in open vessels, from which the thin film of otto is skimmed with a feather in the morning. Twenty thousand flowers are required to yield otto equal to the weight of one rupee, which even in India is worth about 100 rupees, or £10 sterling. Otto is said to have been first procured by what may be called an accidental distillation of rose-petals exposed with water to the heat of the sun, and to have been found floating on the surface of the water; and it is still sometimes obtained in India by such a process. It is said to be also obtained by dry distillation of rose-petals at a low temperature. During the distillation of rose-petals, a small quantity of a solid volatile oil comes over (Solid Oil of Roses, see below), which crystallises and floats on the water in the receiver, and which is sometimes called *English Oil of Roses*. Otto of roses is not unfrequently adulterated with sandalwood oil, oil of rhodium, &c. It is much used for making hair-oil, a drop of it being enough to impart a pleasant odour to a considerable quantity. It is also used in making lavender-water and other perfumes. The odour of otto itself is too powerful to be altogether pleasant. Another method of obtaining the scent of roses is described in the article PERFUMERY. Otto of roses is a mixture of two volatile or essential oils; the one solid at ordinary temperatures, and the other liquid. The solid oil of roses (rose camphor, stearoptène of oil of roses) exists separately in crystalline plates, melts or fuses at 203° F., and boils at about 592°. It possesses of itself very little odour, is insoluble in alcohol, but soluble in ether. It is composed of carbon and hydrogen. The liquid oil of roses (éléoptène of oil of roses) is a very fragrant liquid, to which the otto of roses is indebted for its delicious perfume, and appears to consist of carbon, hydrogen, and oxygen; though its composition and properties have not been attentively studied. The otto of roses may be regarded as a solution of one part of the solid oil in two parts of the liquid. To separate these oils, the otto is frozen at a temperature below 80° F., and the congealed mass pressed between folds of blotting-paper, which absorbs the liquid oil of roses, and leaves the solid. Another process which may be resorted to is to treat the frozen otto with alcohol, which dissolves the liquid oil, and leaves behind the solid. The otto of roses has a specific gravity of 832, water being 1000; it is combustible; and when its vapour is diffused through oxygen, and set fire to, a violent explosion takes place: 1000 parts of alcohol dissolve 7 parts of the otto in the cold, and 33 parts when slightly heated. The principal use to which otto of roses is put is as a perfume. Milk of roses and lavender-water owe their fragrance to the presence of the otto. A good receipt for oil for the hair is olive oil, coloured by alkanet, and scented by a few drops of otto, and this is very generally sold under the name of otto of roses. Medicines are occasionally perfumed by otto of roses, and it is sometimes added to unguents and spirit-washes.

OUGRÉE, a town of Belgium, in the province of Liège, three miles south-south-west from Liège, on the right bank of the Meuse. It has iron-works,

a cannon-foundry, and oil and flour mills. The neighbourhood produces coal. Pop. (1863) 6086.

OVAR, a town of Portugal, in the province of Beira, 17 miles north from Aveiro, at the mouth of the small river Ovar, and at the head of one of the branches of the curious lagoon or bay called Ria d'Aveiro. See AVEIRO. It is a prosperous and rapidly increasing town, and carries on an extensive fishery and a considerable trade. Pop. (1863) 10,374.

OVEN-BIRD (*Furnarius*), a genus of birds of the family *Certhiadae* (q. v.), natives of the southern parts of South America, interesting on account of the remarkable nests which they construct. They are small birds, with short wings and feeble power of flight. One species, *F. albogularis*, or *F. rufus*, is found near Buenos Ayres; another, *F. fuliginosus*, inhabits the Malouine Islands. It is a fearless little bird, regarding the presence of man so little that it may be easily struck down with a switch. Both sexes take part in the construction of the nest, which is generally in an exposed situation, remarkably large, and of the shape of a dome, with a small entrance on one side, so as to have much resemblance to a rude oven. It is made of clay, grass, &c., well plastered together, and becomes quite firm as the clay dries in the sun. Internally, it is divided into two chambers by a partition

reaching nearly to the roof, the eggs being placed in the inner chamber on a bed of soft grass and

Oven-bird (*Furnarius fuliginosus*).

feathers. The outer chamber seems to be intended for the male.

OZIERI, a town of the island of Sardinia, in the province of Sassari, 26 miles east-south-east from Sassari, amongst the mountains which occupy the centre of the island. It stands in a deep valley, open only to the north, and is therefore peculiarly exposed to cold winds. Pop. (1861) 7143.

P

ADRON, a very ancient town of Spain, in the province of Coruña, 15 miles south-west of Santiago, on the Sar, a few miles from the coast. P. being the place at which the body of Santiago is said to have landed itself, was formerly an important place of pilgrimage. Pop. 6090.

PADULA, a town of South Italy, in the province of Salerno, 52 miles south-east of the town of Salerno, in a mountainous district. Below P. are the ruins of the once famous and magnificent monastery, *La Certosa di S. Lorenzo*, despoiled by the French during their occupation of Calabria. Pop. (1861) 6758.

PAGANI, an uninteresting town of South Italy, province of Salerno. In the church of St Michele is the tomb of Alfonso de' Liguori, founder of the order of the Redemptionists, who died here, 1787. The body is preserved in a glass case. Pop. (1861) 11,175.

PAKS, a market-town of Hungary, in the county of Tolna, 60 miles south-south-east of Pesth, on the Danube. The river is here very winding, and the eastern bank a desert and useless morass. The town is frequently subject to inundations. Pop. 9070.

PALAY (*Cryptostegia grandiflora*), a climbing plant of the natural order *Asclepiadaceae* (q. v.), common in many parts of India, particularly on the eastern coast of Hindustan. It yields a very fine strong white fibre, resembling flax, and which can be spun into the finest yarn. The fibre is obtained

from the stalk; the milky juice contains caoutchouc. P. is one of the most interesting plants which have recently been recommended to notice in India.

PALAZZOLO ACREIDE, a town of Sicily, in the province of Noto, 29 miles south-south-west of Catania, is situated on the brow of a hill, just where it overhangs a deep valley. Near P. are the remains of the ancient *Acra*, founded by a colony from Syracuse, on the site of a Phœnician settlement, 664 B.C. The most curious remains are to be found in some low cliffs beneath the town to the south, where is a series of arched niches, containing figures carved in high relief in the rock. The style of art appears to be archaic Greek, with somewhat of an Egyptian character. Pop. (1861) 8654.

PALMA, or PALMA DI MONTECHIARO, a town of Sicily, in the province of Girgenti, 14 miles south-east of the town of Girgenti, near the south-west coast. It is entirely a modern town, its foundation dating only from 1637. There is a trade in almonds, dried fruits, soda, wine, and sulphur. Pop. (1861) 11,188.

PALME, or PALMI, a royal city of South Italy, in the province of Reggio-Calabria, 20 miles north-north-east of Reggio, on the coast of the Bay of Gioja. The town, by means of its port, carries on an active trade. Pop. (1861) 9140.

PARASITA, or ANOPLURA, an order of insects, to all of which the name *Louse* is popularly given. All live as parasites on quadrupeds and birds. The characters of the order are noticed in the article LOUSE. It remains, however, to be added that the order is divided into two sections; in the

first of which, *Pediculidea*, the mouth is small and quite suctorial; whilst in the second, *Nirmidea*, it is furnished with mandibles and hooked maxillae. The species of the first section are found only on man and mammals; those of the second section, almost exclusively on birds, although one infests the dog. The *Nirmidea* shew much greater activity than the *Pediculidea*. When a bird dies, the birdlice congregate near the beak, and seem disquieted, apparently anxious to change their abode.

PARATY, a seaport town of Brazil, in the province of Rio de Janeiro, on the west coast of the Bay of Angra, 90 miles south-west of Rio de Janeiro city. It has extensive commerce, and numerous distilleries. Pop. said to be 10,000.

PARKESINE, the name given to a substance introduced for manufacturing purposes by Mr Parkes of Birmingham. It is a combination of various vegetable ingredients, the number and proportions of which differ according to the qualities required to be given to the substance. Parkesine was first shewn in quantity at the International Exhibition of 1862. The basis is almost any vegetable fibre—such as cotton or flax waste, old rags, &c. The inflammable nature of these fibres is subdued by the addition of certain mineral neutral salts—sulphates, tungstates, &c. Naphtha is used as a solvent. Another component is oil, animal or vegetable, which may or may not be hardened by chloride of sulphur. The inventor has not made public the exact mode in which the various ingredients are combined; but it appears that the elasticity mainly depends on the oil, and the non-inflammability on the kind of neutral salt employed.

In a paper read before the Society of Arts on the subject of Parkesine, and in a discussion which followed the reading, it was stated that this substance is not affected by sea-water; it does not soften, like gutta-percha, by heat; it is a good insulator of electricity, even at a temperature of 212° F.; it may be made either opaque or transparent, plain or coloured; it will make a very strong joint after fracture; it will resist most of the common acids; its tensile strength is greater than that of india-rubber or gutta-percha. In its hard form, the surface can be so treated as to imitate marble, tortoiseshell, amber, or malachite. It may be moulded, pressed, turned, sawn, planed, carved, rolled, engraved, inlaid, or polished, according to the consistency given to it in the course of manufacture; or it may be made thin enough to use, when melted, as a varnish or protective coating or waterproofing. Among the many articles into which it may be fashioned, are included spinners' rolls and bosses, knife-handles, combs, brush-backs, shoe-soles, umbrella and parasol handles, buttons, bookbinding, tubes, galvanic-battery cells, waterproof fabrics, surgical implements, and telegraphic insulators.—It is probable that the eventual success of compositions such as this will mainly depend on the price at which the material can be supplied per pound, compared with the prices of gutta-percha and india-rubber, the two substances which it is mainly intended to imitate or supersede. The supply of these two is wholly dependent on the sap of certain forest-trees in torrid climates; the mode of obtaining the sap is recklessly wasteful; and it is not yet known how far a continuance of the supply can be relied on.

PARRAS, a well-built town of Mexico, in the state of Coahuila, 470 miles north-west of Mexico, near the east shore of Lake Parras. It derives its name from a species of indigenous vine much cultivated, and has always been celebrated for its wines

and brandies. There are many old Spanish families here. Pop. 8000.

PARRISH'S CHEMICAL FOOD is the popular name for a non-official preparation medicinally known as *Compound Syrup of Phosphate of Iron*, every drachm of which contains 1 grain of phosphate of iron, 2½ of phosphate of lime, besides soda and potash. Mr Parrish of Philadelphia was the first to publish a formula for this very useful compound.

PARTA'NNA, a market-town of the island of Sicily, in the province of Trapani, 36 miles south-west of Palermo, on a slope. Pop. (1861) 11,972.

PA'SMA is the name given to a non-official healing-powder, which is regarded as very serviceable in burns, ulcers, excoriations, &c. It is composed of 30 parts of silica, 12 of magnesia, 6 of alumina, 2 of protoxide of iron, and 50 of starch from the oilgro root.

PATENT LAWS. Since the introduction of the amended Patent Law in 1852 (see **PATENTS**), many manufacturers have boldly advocated the abolition of the patent system altogether; on the plea, that the good results, whatever they may be, are over-balanced by the bad. The great majority of advisers, however, call for further reform, not abolition. The Economic Section of the British Association has discussed this matter during a long series of years. The Society of Arts, also, have had many discussions on the subject; and the arguments *pro* and *con.* will be found at length in the *Transactions* of these bodies. The various Chambers of Commerce throughout the kingdom have likewise debated the subject at length. The actual operation of the system may be briefly illustrated. Mr Bennett Woodcroft, in 1864, examined 100 patents out of those which had been applied for in 1855. Of the 100, he found 98 frivolous in character, of little or no value as to the merit of the inventions; 4 of moderate value; and not one of striking promise. Out of the 100 applications, 70 patents were granted, of which 1 became void at the end of six months, 51 more at the end of three years, and 15 more at the end of seven years—because the patentees declined to pay the successive instalments of fees. There were therefore, in 1863, only 3 patents left out of the 100 which had been applied for in 1855. Mr Woodcroft finds that about the same ratio is exhibited in the whole of the 3000 or so applied for every year. In 100 of the average applications in 1858, he pronounced that there was not one invention of much value, 3 of some, and 97 of little or no value. In 1862, he found 1 of much, 1 of some, and 98 of little or no value. As to statistics of actual numbers, see **PATENT OFFICE, LIBRARY, AND MUSEUM.**

In 1862, a royal commission was appointed to consider the whole subject of the patent laws, and to suggest alterations which might be useful. The commission collected evidence in that and the two following years, and made its Report in 1864. On almost every point, the answers to the queries were of the most conflicting kind. The commissioners accompany the evidence with a series of resolutions and suggestions; but the divided opinion of practical men has hitherto discouraged any attempt to legislate on their recommendations; and the act of 1852 remains still in force.

PATENT OFFICE, LIBRARY, AND MUSEUM. The present organization of these establishments arose mainly out of the act relating to *Patents* (q. v.) passed in 1852. Rooms were rented in Southampton Buildings, London, for the office as reorganised; a superintendent of specifications was appointed; and a plan was adopted for

making the system as useful to the public as possible.

The Office.—All the specifications of patents from the earliest date were examined, and minutely classified according to their contents. The patents from 1711 to 1852 were found to amount to the large number of 12,977; and the specifications of the whole of these were printed between 1853 and 1858. There were a few of earlier date, between 1617 and 1711, but none in so complete a form as to render them worth printing. The whole fill many hundred quarto volumes, with the lithographed illustrations bound in separate folio volumes. The expense of the whole undertaking—for paper, printing, and lithographing—was £92,000; the number of copies printed was small; but any single specification can be reprinted if a demand for it should arise. The next work was to utilise this immense collection by a thorough system of indexing. Three indexes were prepared—*Chronological*, *Alphabetical* (according to the names of the inventors), and *Subject-matter*. Arrangements were at the same time made for printing and indexing the specifications of all patents obtained under the new law (1852); and this has been done year by year. These specifications are sold to the public at the price of paper and print, varying from 1*d.* to about 4*s.*, averaging about 8*d.* each. The printing and publishing are completed within three weeks of the time when each final specification reaches the hands of the superintendent. Any copy of any of these, if stamped and certified, is received in any court of law or equity in the kingdom, in evidence of the patent to which it relates, without the necessity of producing the original document itself. There are generally over 3000 petitions for new patents every year; about 800 of the petitioners usually fail to give notice of their intention to proceed, and 200 more fall away before the actual sealing of the patent; so that, roughly speaking, about 2000 specifications of patents are added to the list every year. Of this number, not more than 500 to 600 over-live three years, the patentees being unwilling to pay the second instalment of duty which becomes payable at the end of the third year; and very little more than 100 are willing to pay the third instalment, due at the end of the seventh year. Practically, therefore, although there are 3000 applications yearly, and although the privilege of the patent extends to 14 years, there are only about 100 that remain in force during the whole period. To render the new specifications equally available with those of older date, three indexes are prepared for each year's collection, of the kinds already described. There has also been prepared a *reference* index to the whole series; giving the number by which each patent is designated, the name of the patentee, the name of the office in which the specification was enrolled, and references to any law-books containing accounts of legal proceedings (if any) which may have arisen in connection with the patent. Taken altogether, perhaps no printed collection in England is more fully and variously indexed than these specifications. Besides this, abridgments have been drawn up of most of the specifications, and will be eventually of all: setting forth, in a few words, the general nature of the invention. These abridgments are collected into 12mo volumes, one to each class of subjects; and the volumes are sold at 6*d.* to 10*s.* each, according to their bulk. By reference to one of these handy volumes, or to the *Subject-matter* index, an inventor can see whether any person has preceded him in the particular subject for which he desires a patent.

The Library and Reading-room.—Special arrangements are made to render the specifications, and all

that relates to them, as available as possible to the public. Complete sets of the printed specifications, indexes, &c., have been presented to universities, government offices, provincial towns, colonies, and foreign governments, to the number of far more than 100 altogether—each set comprising more than 2000 volumes. At the head office in Southampton Buildings, a Reading-room has been provided, open to such of the public as may wish to consult the specifications at their leisure. But besides this, the commissioners have gradually become possessed of a large and valuable collection of scientific and technical books and periodicals, to which additions are every year made by purchase. A new Library and Reading-room, occupying the upper part of the old building, has been constructed at a cost of £15,000, and was finished and opened in 1867. All the scientific and technical works of the Library, as well as the specifications of the patents, may here be consulted under due regulations.

The Museum.—The commissioners having come into possession, by gift and otherwise, of several models illustrating patented inventions, had no place of their own to deposit them for preservation and exhibition. But an arrangement was made with the authorities at South Kensington for the reception of these models; and, greatly augmented, the Patent Museum now occupies a site adjacent to the South Kensington Museum. Arranged on tables, walls, and floor are models and specimens of a large number of patented inventions; while in adjacent recesses, and wherever room can be obtained for them, are displayed mechanical drawings and diagrams of various kinds, and a large collection of portraits of celebrated inventors.

The commissioners have for many years sought permission to erect a large and handsome building to accommodate the whole of their departments—offices, Library, Reading-room, and Museum. They possess the pecuniary means, but lack the authority. Their receipts exceed £100,000 a year, in the form of fees from patentees; and after a very liberal expenditure for salaries, superannuation allowances, editing, compiling, printing, purchase of books and periodicals, &c., there is a considerable surplus. A clause in the act of 1852 prevents them from buying land and erecting buildings without the consent of the Treasury; and that consent had not been given down to the end of 1867, except for the new Library and Reading-room.

PATERNO (anc. *Hybla Major*), a town of Sicily, in the province of Catania, and 11 miles north-west-by-west from Catania, at the southern base of Mount Etna. Near P. are salt-springs and a salt-mine. Pop. (1861) 13,961.

PATTI, ADELINA, a popular operatic singer of Italian extraction, born at Madrid in 1843. After a course of professional study under her brother-in-law, Maurice Strakosch, she sang at an early age at New York. Her *début* in London took place in 1861 as Amina in *La Sonnambula*, when she was greeted with rapturous enthusiasm: and she has ever since been looked upon as one of the very first singers of the day. Her voice is an unusually high soprano, of rich bell-like quality, and remarkable evenness of tone; to these qualities she adds purity of style and high artistic finish. Equally at home in the tenderness of deep passion and the sprightly vivacity of light comedy, she has also sung with success in oratorio. Mademoiselle P. has also won golden opinions on the continent wherever she has appeared. Her greatest success is generally considered to be in the part of Marguerite in Gounod's *Faust*, in which she first appeared at Covent Garden in 1864.

PATTI, CARLOTTA, sister of the above, is also one of the leading singers of the day, though a slight degree of lameness has prevented her from appearing much in opera. Her voice is a soprano of unusual compass, and of a clear silvery quality, and much power in the upper register. Her peculiarly high notes, and a graceful *abandon* of manner, have brought her into favour with the public, though, in equality of tone, she does not come up to her sister. She made her *début* in London in 1862, but had for some time before been in the enjoyment of a high reputation in the United States.

PAUCHO'NTI TREE (*Isonandra polyandra*), a large forest-tree, of the same genus with the gutta-percha tree, and producing a substance similar to gutta-percha, abundant in some of the forests at the base of the Western Ghats in India. It is now supposed that there are several species of *Isonandra* in Western India, the produce of all which has begun to be sent to the market as gutta-percha, although it is said that none of the kinds is equal in quality to the true gutta-percha, obtained from *Isonandra gutta*. The wood of the P. tree is very heavy, and its tenacity is equal to that of teak. A P. tree having been tapped in 40 places, from the base to 60 feet high, has yielded in twelve hours about eight pints of sap, each pint being equal to about a pound of gutta-percha.

PAZ (LA) DE AYACU'CHO, a town of Bolivia, South America, capital of a dep. of the same name, about 20 miles from the south shore of Lake Titicaca, is situated on the east declivity of the Andes, at an elevation of 12,000 feet above the sea, on both sides of a deep ravine, here crossed by nine bridges. The whole city is subdivided into sections by numerous ravines. The streets are generally irregular and steep; there are some good public buildings, several educational institutions, a noble cathedral, and many other churches. It is the seat of a bishop and a university. La P. is the largest city, and the principal commercial emporium of Bolivia—the exports consisting of gold, bark, and other products of the country; and the imports of manufactured goods, the bulk of which comes through Peru. This city, whose original name was Nuestra Señora de la Paz, was founded in 1548. The name was changed in 1825 to its present form, in honour of the national victory of Ayacucho (q. v.). Pop. (1858) 76,372, the greater part of which is Indian. Pop. of dep., 475,322.

PE'GANUM, a genus of plants of the natural order *Zygophyllaceæ*, of which the only known species, *P. harmala*, a half-shrubby plant with linear, smooth, almost bipinnatifid leaves, and solitary, white, axillary flowers, a native of the Levant and the north of India, is sometimes cultivated in gardens under the name of SYRIAN RUE. The seeds are narcotic, and the Emperor Solymán is said to have kept himself intoxicated by eating them. They were formerly used in medicine in Europe, and still are in the East. The Turks use them as a spice, and also for dyeing red. The plant is believed to be the *Harmala* of the Greeks, mentioned by Dioscorides as one of the kinds of *Peganon*.

PEI'SHWA (Minister) was the title of the personage third in rank and authority at the court of the Mahratta Maharajahs of Satara, there being only the *Priti-nidhi* (Delegate of the Rajah) between him and his sovereign. However, during the weak reigns of Sevajee's descendants, the minister increased in importance, till, at the commencement of the 18th c., BALAJEE BISHWANATH, the then Peishwa, and a man of distinguished administrative ability and diplomatic talents, made himself virtually the ruler of the Mahrattas (q. v.).

PELLESTRINA, a town of Venetia, near the centre of an island of the same name, 12 miles south from Venice. The island is about 7½ miles in length, and one mile in breadth. It is one of the low narrow islands which separate the Lagoon of Venice from the Adriatic. The island is in great part occupied by a row of small towns, of which P. is the largest. Pop. 7195.

PE'MBA, called the Green Isle by the Arabs, an island off the east coast of Africa, in the dominions of the Sultan of Zanzibar, the nearest point being about 20 miles from the coast, and the southmost point 40 miles north of the island of Zanzibar. It lies across the 5th degree of S. lat., and in long. 39° 53' E. Length about 38 miles from north to south. Next to Zanzibar, P. is the most remarkable island in the dominions of the sultan. It is an irregular coralline island, cut up in every direction by creeks, which are much frequented by country craft engaged in the slave-trade; while, owing to the numerous reefs and shoals, and to the imperfect survey of the island, they are quite impracticable for vessels of war. The vegetation is most luxuriant. Although the main island is less cultivated than Zanzibar, it appears, if possible, more productive, and its fruits, especially the mango, are more highly esteemed. P. is more unhealthy than Zanzibar, and the mortality from fever is so great, that it is a question whether it could be kept under cultivation were the supply of slave-labour cut off. Chak-Chak, the chief fort, port, and town, is situated in a deep inlet on the western side, and the narrowest part of the island. Its approach is winding and difficult. The Portuguese long made P. one of their principal slave depôts. A few merchants reside on the island.

PENEDO, a flourishing town of Brazil, in the province of Alagoas, 50 miles south-west of Macayo, on the San Francisco, near its mouth. In the district, cotton, rice, and other crops are grown. Pop. of town 9000, of district, 17,574, mostly Indians.

PEREJASSLA'VI, an ancient town of Russia, in the gov. of Poltava, 100 miles south of Tchernigov, at the confluence of the Trubesh and Alta, near the Dnieper. A battle was fought here in 1149. Pop. (1863) 10,047.

PERFECTIONISTS, or BIBLE COMMUNISTS, popularly known as FREE-LOVERS, or preachers of Free Love, a small American sect of recent origin, equally remarkable for the doctrines which they hold, and for the unfastening way in which they carry them out in practice. The founder of the sect, John Humphrey Noyes, is still alive, and is described in a recent work (*New America*, by W. Hepworth Dixon) as 'a tall, pale man, with sandy hair and beard, gray dreamy eyes, good mouth, white temples, and a noble forehead.' In appearance, he is a little like Mr Carlyle, and he is said to be not a little proud of the resemblance. Noyes was born at the town of Putney in Vermont; he studied at Dartmouth College, Connecticut, where he took a degree; and he afterwards became a clerk in a lawyer's office at Putney. In 1831, a revival of religion broke out at Putney, and Noyes was one of those who were aroused to a consciousness of sin and anxiety about the way of salvation. He began to puzzle over theological questions; and he gave up the law to study theology at Andover, in Massachusetts. There he found himself exposed, through the habits prevailing among his fellow-students, to many temptations, and notwithstanding his strong religious impressions, he yielded to them very freely. From Andover he passed to Yale College, New

Haven, where he was first a student, afterwards a preacher in connection with the Congregational body, and where he became a great seeker after truth—not as it stands between God and man only, but as between man and man. Here it was that he arrived at the principal of the ideas which constitute his social and religious system—deriving them, after much study and speculation, from the writings of St Paul. He came to the conclusion that the opinions of St Paul had been completely misconceived by all the Christian churches; that all our ecclesiastical organisations have consequently been blunders; and that from the apostolic age to his own there had been no visible church of Christ upon earth. He conceived that in the age of Paul and Peter there had been a true Christian church—a communion of saints, in which all were brethren, and all equals; but that it passed away at an early date, on our Lord having returned in the Spirit, as he had promised, to dwell among his people for ever. This second advent of Christ he placed in the year 70; and he came to the conclusion, that since then the true church has consisted, not of any of the religious organisations which have successively sprung up, but of saintly persons scattered here and there, sinless in body and soul, confessing Christ as their Lord, professing holiness, rejecting law and usage, and submitting their passions to the Divine will. He believed that Christ, on his second advent, abolished the old Law, and closed the reign of sin which began with Adam; and that he has thenceforth set up His kingdom in the hearts of all willing to accept His reign. For such persons, there was no longer any law or rule of duty; neither the Mosaic code, nor the Sermon on the Mount, nor the ordinances or institutions of civil society, were binding upon them; they were a law unto themselves; they were free to do as they pleased, but—with exceptions which, however, could not invalidate an eternal truth—under the influence of the Divine Spirit which dwelt in them, they could only do that which was right. It was owing to the power of the devil that the churches had gone so far astray; but he conceived that the time had come when, among the new communities of America, there should be set up a perfect model of a Christian church—in which all should be brethren; in which men and women should be equals; in which individuals should be untrammelled by any restraints save those imposed by the Divine Spirit working within themselves. Noyes took upon himself the task of laying the foundations of the true Christian church; but before setting to the work, he furnished at once evidence of his belief in his theory, and an illustration of the dangers attending it in practice. At Yale, while his theory was forming, his life had been regular, and even exemplary: his mind once satisfied that there was no law for him, he gave the rein to dissipation, and for some time abandoned himself to the wildest licentiousness.

His early efforts at establishing a church, made at New Haven, were very discouraging; he made converts to his views, and they became only too deeply imbued with his theory. Each being a law unto himself, they had conflicting desires, and this led to quarrelling, and eventually to schism. Among the men, there were some who contested with Noyes the leadership of the fraternity; and among the women, one or two who, in spite of his theory, expected him to marry them. At the end of four years, he found, that though he had co-believers, he had no followers; and he retired to Putney, his native town, disappointed, but resolved to make a new experiment. He determined to make trial of the principle of association—of association under conditions which he deduced from

the New Testament; to establish a 'Bible Family'—a society disavowing all law and all connection with the world, in which all should be brethren, perfectly equal; in which, therefore, worldly goods should be held in common; in which there should be no appropriation of men and women to one another. The connection of the sexes was, upon his view, as free from law, as completely subject to the desires of individuals, as every other human relation; and besides, he seems to have thought a community of women a logical sequence from a community of goods. He saw that the members of such a society must be selected and educated for it; and he set up a Bible class, by means of which he gained a sufficient number of proselytes, and educated them for Bible association. Before long, there was nothing wanting for a trial of his scheme but money to buy a house and a piece of land; and this he got by marrying one of his converts, a young lady named Harriet Holton, to whom it is but fair to say, he candidly explained that with his principles marriage could be nothing but a form. Then he and his associates formally renounced their allegiance to the United States, and set up house in 'celestial order' at Putney. His wife, mother, sister, and brother were among the members of the new society; the others were all persons of some means and position—preachers, farmers, doctors, with their wives and children. Their property was thrown into a common stock; they gave up the use of prayer, all religious service, and the observance of the Sabbath; those who were married renounced their marriage ties, and a 'complex marriage' was established between all the males and all the females of the 'Family.' To get rid of the inconveniences which had been found attendant upon the exercise of Christian liberty, Noyes had set up a new principle, viz., sympathy, by which the individual will was to be corrected, which practically imposed upon individuals the duty of deferring to the feelings and opinions of the brethren. He now taught that the Family was wiser than the individual, who might stray from the path of grace; that the individual was erring when he differed from the Family; and that the inclinations of individuals must be submitted to the opinion of the Family. Having dispensed with law, he set up public opinion as a controlling power in its stead; and free criticism of one another by the members of the society became an important feature of his system. Quarrelling, however, broke out among the members; their differences were brought before the law-courts; and when the details of the Family system became known, the people of Putney made the place too hot for the Perfectionists. Their establishment was broken up; but a portion of the Putney Family—about fifty men, as many women, and about the same number of children—soon established themselves in a new home, in the sequestered district of Oneida, in the state of New York. Among the things which first drew attention to the Putney Family was a controversy which Noyes maintained with the leaders of another society of P. established at Oberlin. The P. were divided upon the question, whether of the two leading features of their system, the profession of holiness and the right of Christian liberty, the one or the other was the more important—some were 'Liberty-men,' others 'Holiness-men.' Noyes took up the controversy on behalf of the latter.

At Oneida Creek, the new 'Family' purchased about 600 acres of forest-land, and proceeded to bring it under cultivation. They have made it one of the most productive estates in the Union; they have also established manufactures of various kinds; and in the course of 20 years, they have become a

prosperous, and even a wealthy community. Their wealth they owe in a great measure to the inventive talent of one of the 'Family,' an old Canadian trapper, named Sewell Newhouse, who invented an improved form of trap—the 'Oneida Trap'—which is now almost universally used by trappers throughout America. In other respects, the 'Family' has been very prosperous: it now consists of nearly 300 persons, who live together harmonious and contented; and being already sufficiently numerous, it has to reject frequent applications which are made for admission to membership. Two similar societies have been established—the one at Wallingford, the other at Brooklyn—and both are said to be doing well. Their neighbours have become accustomed to the P. and their ways, and let them live in peace; Noyes is even become popular. On settling at Oneida, guided by his experience, he modified many of the details of his arrangements. Between study and labour, the life of the 'Family' at Putney had been rather a hard one—he told his followers that in future they should enjoy life, as became men to whom all things were pure and permitted. The society chose no chiefs, believing that, without chiefship, the management of their affairs must fall to the fittest persons; and their affairs have been ably managed. The controlling function of criticism was strengthened by being made more systematic; and a regard for the common good, grown strong through habit, has made persons who disavow all laws perfectly submissive to the unwritten laws of public opinion. In the smallest, as well as in important affairs, the Perfectionist practises submission to the opinion of his brethren: in small matters, he usually gathers it by consultation with some of the older members of the body; important ones are submitted to the 'Family' at their evening meetings. All are busy; and they work as hard for the general interest as men do in the hope of enriching themselves. The men wear no particular garb, but usually dress like the country-people around them; the women have their hair cut short, and parted down the centre; shjure stays and crinoline; wear a tunic, falling to the knee, and trousers of the same material; a vest, buttoning high towards the throat; and a straw hat. In this costume, according to Mr Hepworth Dixon, plain women escape notice, and pretty girls look winsome; but, as may be inferred from the treatment of their hair, it has been no part of the Perfectionist system to make the women look bewitching. The 'Family' has breakfast at six o'clock, dinner at twelve, and the evening-meal at six in the afternoon; the more advanced of its members abstain from animal food; they drink no beer, and only a weak home-made wine; and like most of the new American sects, they will have nothing to do with doctors. The women are allowed a good deal of influence.

While all the males and females of the 'Family' are united by a 'complex marriage,' their intercourse—which, in theory, is unfettered by any law—is, in practice, subject to a good deal of regulation. Like everything else, it is subject to the opinion of the society, and certain principles have been so steadily applied to it, that they have gained the force of laws. First, there is the principle of the ascending fellowship. There should be contrast, the P. say, between those who become united in love. That there should be difference of temperament and of complexion has, they say, been well ascertained by physiologists. They hold that there should be a difference in age also, so that the young and passionate may be united to those who have, by experience, gained self-control. In virtue of this principle, the younger women fall to the older men, and the younger men to the older women. A second

principle is, that there should be no exclusive attachment between individuals; a third, that persons should not be obliged to receive the attentions of those whom they do not like; and lastly, it is held indispensable that connections should be formed through the agency of a third party—because, without this, the question of their propriety might be withdrawn from criticism, and also, because this affords a lady an easy opportunity of declining. The human heart, the P. say, is capable of loving any number of times, and any number of persons at the same time, and the more it loves the more it can love. The system of the 'complex marriage' is therefore suitable to, while monogamy imposes a restriction upon, human nature; and they believe that marriage will be spurned by the churches as soon as they get rid of the false notion of the essential sinfulness of love. They are confident that, when they have worked out a few details, still incomplete, their system will be perfect, and that it will, before long, be imitated throughout the length and breadth of America. The former failures of communism they ascribe to the previous experiments not having been founded upon Bible truth; to their being made by persons unprepared for the system; and to the attempt to combine the monogamous family with the community of goods. There are four things, according to Noyes, necessary to the organization of a true family: (1) the reconciliation of its members with God; (2) their salvation from sin; (3) recognition of the brotherhood and equality of man and woman; (4) community of labour and its fruits; and communism can only prosper when the previous conditions exist. The P. hold that for reconciliation to God and salvation from sin nothing is necessary but faith; let a man believe that he is reconciled to God, and his sins are immediately washed away; and if, in addition to 'confessing holiness,' he submits his will, through sympathy, to the decision of his brethren, he is fit to be a member of a true family, which acknowledges no law, and has everything in common.

PERLEBERG, a town of Prussia, in the province of Brandenburg, gov. of Potsdam, on the Stepnitz, 74 miles north-west of Berlin, and a few miles from the Magdeburg and Hamburg Railway. There are some woollen manufactures. Pop. (1864) 7701.

PERUWELS, a town of Belgium, in the province of Hainaut, near the French frontier, 44 miles south-west of Brussels. It has breweries, limekilns, and some linen manufactures. Pop. (1863) 7857.

PETTERHOF, a palace of the emperor of Russia, on the southern shore of the Gulf of Finland, 15 miles west of St Petersburg, with which it is connected by railway. The palace was built by Peter the Great in 1711, is still often resorted to by the imperial family, and is the scene of great occasional festivities. It contains a very fine collection of paintings, and is surrounded by fine gardens and a beautiful park. Around the palace, a village soon grew up, which has become a town of (1863) 7055 inhabitants.

PETŐFI, SANDOR (ALEXANDER), who may fairly be described as the national poet of Hungary, was born at Little Körts, in the county of Pesth, in 1822. His father was a butcher, and a small landowner in Little Kumania, and bore the name of Petrovich (son of Peter)—a name indicating a Slavonic origin, which the poet, when he came to manhood, exchanged for the Magyar equivalent, Petőfi. In 1833, his father was reduced to poverty by an overflowing of the Danube, which destroyed his little estate; and it was by the help of relatives that he was able to carry out his design of educating his son for a

profession. P. was sent to the lyceum of the town of Schemnitz. It was while there that he began to write verses, and first displayed the extravagant fondness for theatricals which characterised him throughout life. From the first, he neglected his studies; ultimately, he ran away with a band of German strollers. His father after some time found him out, and brought him home, and he remained for a period in quasi-custody among his relatives. When at length he was again sent to school at Oedenburg, he almost immediately ran away, and enlisted as a common soldier. After he had been about two years in the army, a physician, who had taken pity upon him, procured his discharge, and he went back to his relations. He afterwards went to Pápá, to complete his education. His passion for the stage, however, drew him away from Pápá, as it had formerly done from Schemnitz; in 1842, he left it to join a troop of comedians. His stage-attempts were utter failures, and he soon parted from the comedians, if, indeed, he was not dismissed by them. He made his way to Presburg, and afterwards to Pesth, where he got some employment as a translator from the English and the French. Among other works, he translated a novel by Mr G. P. R. James. As soon as his literary labour supplied him with the means of travelling, his passion for the stage returned upon him; he went to Debreczin, and made another venture as an actor—playing the part of Othello—but failed even more completely than before. At last he had the good fortune to be invited to contribute to a newspaper at Pesth—the *Devallap*—and he immediately closed with the proposal. He made his way on foot from Debreczin to Pesth—a distance of nearly 200 miles—wearing shoes padded with straw, and carrying in his bosom a MS. volume of verses, his whole provision for the journey consisting of two florins, which he got from an old school-fellow. It was on his arrival at Pesth that he exchanged the name of Petrovich for Petöfi. Within a few weeks of his arrival, he had troops of friends and a reputation.

He introduced himself to Vörösmarti, then the most popular poet of Hungary, who received the shabbily-dressed stranger coldly, and did not readily consent to listen to his verses. But when he had listened, he expressed his admiration warmly. 'Hungary,' he exclaimed, 'never had such lyrics: you must be cared for.' And from that time, he treated P. as a son, and never rested until his merits were fully acknowledged by his countrymen. P. was almost at once received into the Literary National Circle, at the expense of which was published his *Versek*, which appeared in 1844. This was soon followed by other volumes, which succeeded each other with amazing rapidity; all of them, though regarded as vulgar by some of the critics, obtaining an unbounded popularity; so that it was said of P. that 'he never went to bed at night, he never arose in the morning, without hearing his songs from the multitudinous passengers in the public streets.' He sprang almost at a bound into a position in Hungary similar to that which Burns holds in Scotland—that at once of the greatest poet and the representative man of his country. In 1848, when the revolutionary movement, which spread over Europe, began to affect the Hungarians, his energies and enthusiasm found a more useful direction; he became, by speech and pen, the advocate of the independence of Hungary. He was for some time a member of the Diet, but in October 1848, he became a captain in the Hungarian army; and in the beginning of 1849, he was appointed adjutant and secretary to General Bem. He was present at the

battle of Segesvár, fought on July 31, 1849, in which Bem's army was defeated with great slaughter; and he was never heard of after that battle. It is believed that he was trampled to death in the flight, and that his body, so defaced as to escape recognition, was buried with the multitude of Magyar dead left upon the field. His countrymen long believed that he was not dead, but a prisoner in an Austrian dungeon; and it is said that among the peasantry this belief is cherished still. Several false Petöfis have made their appearance since his death, and much spurious poetry has been published under his name. Lately, however, his countrymen have subscribed for the erection of a monument to his memory, and have purchased, with a view to its preservation, the house in which he was born at Little Körös. He left a widow—who has married again—and one son. His brother, STEPHEN, has gained some reputation as a poet.

His poems, 1775 in number, were published in ten volumes. Most of them are lyrics, of which he published several collections, under the titles, *Cypress Leaves on Ethelka's Grave*; *Pearls of Love*; *Starless Nights*; *Clouds*. The most celebrated of his narrative poems—also the longest—are, *János, the Hero*; and *Istok, the Fool*. His earliest work was *The Village Hammer*, published in 1843; his latest, *The Assessor of the Judgment-seat*, which appeared in 1849. A volume, containing a poem entitled *The Apostle*, was suppressed by the Austrian government after the pacification of Hungary. P. published a novel, *The Hangman's Rope*, which was by no means successful, and several volumes of tales, criticisms, and sketches of travel; and he translated largely from English and French into the Magyar.

A selection from his earlier pieces, translated into German, was published in 1845; and several volumes of translations from his writings have since appeared in Germany. They have also been translated into French, Flemish, Polish, Danish, and Italian; and lately, an English version, comprising his finest poems, has been published by Sir John Bowring. The quality of his poetry has been as fully recognised among foreigners as among his countrymen: thus, Grimm declared that 'Petöfi will rank among the very greatest poets of all times and tongues;' Henry Heyne spoke rapturously of his 'rustic song, sweeter than that of the nightingale;' and Uhland avowed that only old age could prevent his learning Magyar, that he might enjoy P. in his native dress.

PETROV'SK, a town of Russia, in the province of Saratov, 55 miles north-west of Saratov, situated on the Medveditz, a tributary of the Don. Pop. (1863) 9229.

PEUTINGERIAN TABLE, the name given to a most interesting ancient document, which exhibits the military roads of the Roman Empire, and indeed of the world known to the Romans. It is not, properly speaking, a map; no regard being paid to geographic position, or the extent of countries. The great lines of road are laid down in a narrow strip, as if nearly parallel, all proceeding from Rome as a centre; and as to rivers, it only appears whether they cross the road from left to right or from right to left of the traveller proceeding from Rome. The Mediterranean and other seas are represented by mere narrow channels. A small house is the mark for a town; important towns and military stations are distinguished by walls and towers. Rome, Constantinople, and Antioch are each represented by a circle, within which is a human figure seated; in the case of

Rome, the figure is crowned. Until very recently, a portion of the only copy of this valuable relic of antiquity known to exist was evidently wanting, as it terminated abruptly on the west at the confines of Spain, and included only the eastern parts of Britain. In the east, it traces roads through India to a number of places of trade as far as the mouths of the Ganges. It is on parchment, and as described in all the publications devoted to it, twenty-one feet in length, and about one foot wide. It was found in the library of the Benedictine monastery at Tegernsee, in Upper Bavaria, in the 15th c., by Conrad Celtes, who bequeathed it to Conrad Peutinger of Augsburg, a zealous antiquary, and one of the earliest authors on the Roman and other antiquities of Germany. Peutinger began to prepare a copy of it for publication, but died before he could accomplish his purpose, which, however, was partially executed by Mark Weiser, in his *Fragmenta Tabulæ Antiquæ ex Peutingerorum Bibliotheca* (Venice, 1591). The ancient document itself remained in the hands of the Peutinger family, and attracted no further notice, till it was offered for sale in 1714, and purchased by Prince Eugene, who presented it to the Imperial Library of Vienna, in which it still remains. An exact copy of it was published at Vienna in 1753, with an introduction and index by F. C. von Schoeyb. It was again published as an appendix to Katsenich's *Orbis Antiquus* (Ofen, 1825); and at the request of the Academy of Munich, a revised edition, with an introduction, was published by Conrad Mauuert (Leip. 1824). Since that time, a leaf detached from the rest has been found in the Imperial Library at Vienna, but we are not aware that any particular account of it or its contents has yet been given to the public.

The Peutingerian Table does not always agree with the Antonine Itinerary (see ITINERARY); some stations and towns being marked in the one which are not in the other, the distances marked being also sometimes different. But the two together throw great light on ancient geography. It appears almost certain from internal evidence that the Peutingerian Table belongs to the third century of the Christian era, or the beginning of the fourth, although the existing copy seems to belong to a later date. The general character of the work seems to shew that its authorship is to be referred to times of prevalent paganism; whilst a few things appear, probably alterations or insertions of a copyist, which refer to Christianity.

PHARMACOPEIA (supplement to the article). The *British Pharmacopœia*, published in 1864, had the merit of amalgamating the London, Edinburgh, and Dublin Pharmacopœias; but it unfortunately contained so many defects, that, in accordance with the universal wishes both of the medical profession and of the chemists, the Medical Council ordered a new edition to be as speedily as possible prepared. This new edition has met with general favour from the profession; and it is to be hoped that as we have now succeeded in incorporating three distinct works into one, we may, in the course of a few years, hope to have a universal Pharmacopœia, or, at all events, one of so general a nature that the most important medicines of the American, British, and chief continental Pharmacopœias* shall all be of the same strength. The most important additions to the new edition are benzoated lard (used for making suppositories and ointments), bromide of

ammonium (useful for sleeplessness, and in hysteria and epilepsy), carbonate of bismuth and solution of citrate of bismuth and ammonia (useful in the same cases as white bismuth), iodide of cadmium (which may be used in the form of ointment when the yellow colour of the skin that follows the application of iodide of lead ointment is objected to), oxalate of cerium (which, in doses of one or two grains three times daily, acts as a sedative and tonic, and is of great value in chronic intestinal irritation, dyspepsia, pyrosis, in chronic vomiting, and especially in the vomiting during pregnancy), flexile collodion (consisting of a mixture of 48 parts of collodion, 2 of Canada balsam, and 1 of castor-oil, and useful as a protecting coating for burns, ulcers, and in erysipelas); glycerines of borax, carbolic acid, gallic acid, tannic acid, and starch (which are used as local applications); various mercurial preparations, as compound ointment of mercury (which is an imitation of Scott's celebrated ointment for diseased joints), mercury suppositories (for thread-worms in the rectum), and the black and yellow washes which are now for the first time made officinal, lozenges of chlorate of potash, tincture of pellitory or pyrethrum (used locally for relieving toothache), quinine pills and wine, tincture of sumbul (valuable in 20 minim doses as a nervous stimulant in typhoid fever, delirium tremens, &c.), and tincture of green hellebore, or *Veratrum viride* (which, in doses of from 5 to 20 minims, is useful in gout, rheumatism, and neuralgic affections).

PHILIPPO'POLIS, a town of Rumili, European Turkey, in the eyalet of Adrianople, 91 miles west-north-west from Adrianople. It stands on a small island formed by the Maritza, which here becomes navigable. This island rises as a hill in the midst of a vast plain, which extends beyond Adrianople on the east, and from the base of the Rhodope Mountains on the south, to the Balkan chain on the north. The plain is extremely fertile, and is celebrated for the excellence of the rice which it produces. P. carries on a very extensive commerce both with Austria and with the East. P. is an ancient town, and in the time of the Romans bore the name of *Trimontium*. Three-fifths of the inhabitants are Christians, one-fifth Jews and gipsies, the remainder Mohammedans. P. is the seat of a Greek archbishop. The North American Board of Missions has a station at Philippopolis. Pop. about 60,000.

PHILIPPSBURG, a town of the grand duchy of Baden, 16 miles north from Carlsruhe, on the right bank of the Rhine, at the mouth of the Salz-bach. In former times, it was one of the most important fortresses on the Rhine, and belonged to the Bishop of Spire. During the Thirty Years' War, P. fell successively into the hands of the Swedes, the French, the Imperialists, and again of the French, who were confirmed in possession of it by the Peace of Westphalia. In the war between Louis XIV. and Germany, it was taken by the Germans under Duke Charles of Lorraine, and assigned to Germany by the peace of Nimeguen in 1679; but was again taken in 1688 by the French under Vauban, and once more restored to Germany by the peace of Ryswick in 1697. The French captured it again in 1734, and this time with little difficulty, the strength of the fortress being now much diminished, although the capture cost the life of the Duke of Berwick, their commander; and they again relinquished it in 1735. During the wars of the French Revolution, P. was bombarded in 1799, taken, and its fortifications completely destroyed in 1800. Pop. (1864) 2317.

PHULOW'DI, a town of India, in the Rajpoot state of Jodhpoor, in lat. 27° 8' N., and long. 72° 28' E.

* The chief continental Pharmacopœias are the French, which is also used in Switzerland; the Prussian, which is mostly used in Germany and Russia; and that of Orsoi, which is used in Italy.

It is built on a rising ground, near the bank of a stream, which, after a course of no great length, loses itself amidst the sands of the desert. Pop. about 15,000.

PIANA DE' GRECI, a town of Sicily, in the province of Palermo, 10 miles south-west from Palermo, on one of the head-waters of the Belici. It was the chief colony of the Albanians who settled in Sicily in the 15th c., taking refuge from Turkish tyranny. Twenty-three such colonies were established in Calabria, but only four in Sicily, where King John II. granted them land, and guaranteed to them the free exercise of their religion. The colony at P. was founded in 1488. The descendants of the colonists still follow the Greek ritual, and adhere to all the customs of the Eastern Church, although acknowledging the supremacy of the pope. The Albanian dress is partially retained among the poorer classes, and particularly among the women. The inhabitants of P. are mostly husbandmen and shepherd. The houses are generally mean buildings of a single story. Pop. (1861) 7270.

PIATRA, a town of Moldavia, 62 miles west-south-west from Jassy, on the left bank of the Bistritza, a branch of the Sereth. The church of P. is one of the oldest in Moldavia. The only paper-mills in the province are here. Much wood is floated down the Bistritza and the Sereth to the Danube, to be exported from Galatz. Pop. (1860) 11,805.

PIAZZA, or, more fully, **PIAZZA ARMERINA**, a town of Sicily, in the province of Caltanissetta, 17 miles east-south-east from Caltanissetta. It stands on the crests and slopes of an isolated hill on the left bank of the Terranova. It is the residence of many nobles and landowners. The chief trade is in corn, oil, fruits, and other agricultural produce. Pop. (1861) 20,310.

PICTURES, RESTORATION OF. Some important observations on the action of light on oil-paintings have led to a series of experiments by Dr David Price of the Crystal Palace, and he has succeeded in demonstrating that the discoloration of pictures in galleries and dwelling-houses arises in a great measure from the presence of sulphide of hydrogen gas, which reduces the metal in the white lead, and thereby gives the dark dingy appearance which so frequently defaces even modern pictures in some places where the pictures are hung on walls not exposed to the direct light of the sun. Dr Price shows that pictures which have been thus injured can be completely restored by being fully exposed to light in a pure atmosphere, the light exerting a rapid and powerful influence over the lead compounds, even though well protected with varnish. The same holds good even in a stronger degree in water-colour paintings in which lead-whites have been used.

PIEDIMONTE D'ALIFE, a town of South Italy, in the province of Caserta, and 20 miles north-by-east from Caserta, at the base of the Apennines, on a branch of the Volturno. It is about 3 miles north-east from Alife, the ancient *Alifan*, a city of the Samnites, now a small town of only 2689 inhabitants. In a grand and gloomy ravine, called the Val d'Inferno, near P., a torrent issues from a cavern, which is supposed to derive its waters through subterranean channels from a lake, about five miles distant, amongst the mountains. This and other mountain torrents afford water-power for a number of cotton, paper, flour, fulling, and copper mills in and around the town. P. is one of the most active manufacturing towns in Italy. The extensive cotton-mills established by Mr Egg give employment to about 1500 hands. There are copper-mines

in the vicinity. Pop. (1861) 7933.—**Piedimonte** is the name of several smaller towns and villages in Italy and Sicily.

PIEDRA BLANCA, a town of the Argentine Republic, South America, in the province of Catamarca, and 20 miles south-west from Catamarca. Pop. (1863) 10,000.

PIETRAPEZZIA, a town of Sicily, in the province of Caltanissetta, and six miles south-east from Caltanissetta, on a lofty height rising from the left bank of the Salso. There are sulphur-mines in the vicinity. Pop. (1861) 10,296.

PILLIBIT, or **PHILLIBIT**, a town of India, in the British district of Bareilly, North-west Provinces, 28 miles north-east-by-east from Bareilly, on the left bank of the Gurrah, and on the road from Bareilly to Petagorah. P. is a place of considerable trade. The P. rice, celebrated throughout India for its excellence, is the produce of the south of Kumaon, brought to P. to market. Pop. 26,760.

PIP, CHIP, or ROUP, a disease of poultry, often very fatal, particularly to chickens and turkey poult. It is very frequent also in young pheasants. Adult birds are, however, liable to it; and when it appears in a poultry-yard, it often attacks many in rapid succession, so that it is regarded as highly contagious. It most frequently occurs in wet or very cold weather, and is generally described as a kind of catarrh, although perhaps it might more accurately be called a kind of influenza. It begins with a slight hoarseness and catching in the breath, which is followed by an offensive discharge from the nostrils and eyes, rattling in the throat, and an accumulation of mucus in the mouth, forming a 'scale' on the tongue. The communication of the disease from one bird to another is supposed to take place through the contamination of the water in their common drinking-vessel; and therefore a bird affected with it should at once be removed from the rest. Castor-oil is freely administered by some poultry-keepers. Mrs Blair, in *The Henwife*, recommends a table-spoonful, but without saying whether this dose is for a full-grown fowl or a young chicken. She recommends also a medicine composed of half a drachm of dried sulphate of iron, and one drachm of capsicum, made into 30 pills with extract of liquorice, one pill to be given three times a day. This after a certain time is to be followed by another compound of sulphate of iron, cayenne pepper, and butter. The eyes, nostrils, and mouth are to be washed with vinegar. In one of the most recent works on poultry (*The Practical Poultry-keeper*, by L. Wright, Lond. 1867), it is specially recommended that the diseased birds should be kept warm; they are to be fed on oatmeal mixed with ale, and to get plenty of green food. In other respects, except as to the castor-oil, the treatment recommended nearly agrees with Mrs Blair's; but the removal of the 'scale' from the tongue is not regarded as necessary, because it will disappear of itself on the cure of the disease.—It is proper to mention that there is considerable confusion of nomenclature as to the diseases of fowls, and that, by some writers, the mere symptomatic affection of the tongue is called *Pip*, and the disease itself *Roup*. The terms, however, are generally used in the same sense.

PIZZO, a seaport of South Italy, in the province of Catanzaro, 24 miles west-south-west from Catanzaro, on the Gulf of Santa Eufemia. It was at P. that Murat (q. v.), the ex-king of Naples, was taken, tried, and shot. He was buried in one of the common vaults of a church to the erection of which he had largely contributed. Pop. (1861) 6402.

PLANETOIDS. The indefatigable zeal of

astronomical observers continues to add to the number of these minute members of the solar system that are now known. *Eighty-one* of them are mentioned under PLANETONDS (q. v.), four more (one of which, the 85th, has since been named Io) under SOLAR SYSTEM (q. v.); the 86th (Semele) was discovered by Dr Tietjen at Berlin, January 4, 1866; the 87th (Sylvia) by Mr Norman R. Pogson, government astronomer at Madras, May 17, 1866; the 88th (Thisbe) by Mr C. H. F. Peters, Hamilton College Observatory, Clinton N. Y., June 15, 1866; the 89th by Mr Stephan, Director of the Observatory at Marseille, August 6, 1866; the 90th (Antiope) by Luther at Bilk, near Düsseldorf, October 1, 1866, being no less than the 15th which that indefatigable explorer has discovered; the 91st by Stephan at Marseille, November 4, 1866; and the 92d (Undina) by Dr Tietjen at Berlin, and by Mr Peters at Hamilton College, Clinton, U. S.

PLASSEY, a small town of British India, in the presidency and province of Bengal, and in the district of Nuddea, 84 miles north from Calcutta, on the left bank of the Bhaghrutti, a river which derives its waters from the Ganges, and pours them into the Hooghly, or rather may be said to become the Hooghly. P. is celebrated in the history of India for the great victory gained by Clive (q. v.) over Suraja Dowlah, subahdar of Bengal, 23d June 1757, a victory, the immediate effect of which was to transfer the subahdarship to Meer Jaffier, but which really laid the foundation of British supremacy in India. The British force at the battle of P. consisted of not much more than 3000 men; and the only British troops were about 650 foot and 150 artillerymen, the remainder being sepoy. The subahdar's force consisted of 18,000 cavalry and 50,000 infantry, with 40 or 50 French artillerymen, 50 large cannon, and 4 pieces of light artillery. On the evening before the battle, Clive held a council of war, at which it was resolved to decline battle, on account of inferiority of force; but Clive himself afterwards adopting a different resolution, crossed the river, and won a most brilliant victory.

PLINLIMMON, or PLYNLIMMON, a mountain of Wales, on the boundary between the counties of Montgomery and Cardigan, 11 miles north-west from Llanidloes. It is 2481 feet in height. The name P. is said to be a corruption of the Celtic *Pumlumon*, signifying Five Rivers, and to be due to the fact, that five rivers have their source in this mountain: one of them is the Severn, and another the Wye. P. is a huge mountain mass, with three chief summits. Although not above 12 miles from the coast, it is in the midst of a wide waste of muir and bog. Spurs, or subordinate mountain-ranges, spread out from it in all directions. The view from the summit is very extensive. It was in the fastnesses of P. that Owen Glendower took his stand, in 1401, at the outset of his career, issuing thence with a few determined followers to make inroads on the English borders.

PLOJESHTEI, or PLOYESTI, a town of Wallachia, 35 miles north-by-east from Bucharest, on the Dimbow, a feeder of the Jalomnizza. It is a place of considerable trade, and has a great annual wool-fair. Pop. (1860) 26,468.

PLUME-BIRD (*Epimachus*), a genus of birds of the family *Upupidae* (see HOOPON), but exhibiting points of resemblance both to honey-suckers and to birds of paradise. The bill is slender and arched. The plumage is magnificent and gorgeous, scarcely excelled even by that of birds of paradise. The plume-birds are natives of New Guinea and New Holland. They are variously adorned with

enormously long tail-feathers, great shoulder-tufts of broad feathers, loose downy plumes, &c. One

Plume-bird (*Epimachus albus*).

species, *E. albus*, has remarkable thread-like prolongations of the shaft of some of its plumes.

POINTA-PITRE, a town of the French West India island Guadeloupe, capital of the division of Grande-Terre, on the Little Cul-de-Sac, 20 miles north-east of Basse-Terre. The town is well built, and has a safe and spacious harbour. It is the centre of the commerce of the colony. Pop. 14,000.

POISSON, SIMON-DENIS, a celebrated French geometer, was born at Pithiviers, in the dep. of Loiret, 21st June 1781; and displaying an aptitude for mathematics, he was received into the Ecole Polytechnique in 1798. The striking talent he thus early exhibited, attracted the notice of Lagrange and Laplace, both of whom anticipated for him a brilliant future. In 1802, he became a professor in the Polytechnique; in 1808, a member of the Bureau des Longitudes; in 1809, Professor of Mechanics to the Faculty of Sciences, member of the Institute in 1812, &c.; and this list of distinctions was crowned in 1837 by his elevation to the dignity of a peer of France. P.'s whole life was devoted to the prosecution of scientific research, and the fruits of his pen number about 300 Memoirs, inserted in the Journals of Ferrussac, Gergonne, Crellé, and Liouville, in the publications of the Ecole Polytechnique, of the Academy of Sciences, of the Bureau des Longitudes, &c. A complete summary of these labours by P. himself is published by Arago (*Notices Biographiques*, vol. ii.). Of the separate treatises published by P., the following are the chief: *Traité de Mécanique* (2 vols. 1833); *Nouvelle Théorie de l'Action Capillaire*; *Théorie Mathématique de la Chaleur* (1835); *Mémoire sur le Mouvement des Projectiles dans l'Air, en ayant égard à la Rotation de la Terre* (1839); and lastly, the celebrated work, *Sur l'Invariabilité des Moyens Mouvements des grands Axes Planétaires*. P. is fairly considered one of the chief founders of the science of mathematical physics, which was brought by him to great perfection, especially in what concerns statical electricity and magnetism. Many other ingenious discoveries and speculations are dispersed throughout his writings.

POKHURN, a town of India, in the Rajpoot state of Jodhpoor, 340 miles south-west of Delhi. It is situated close to a deserted town of the same name, the site of which is marked by a very conspicuous temple in an elevated situation. P. has a pop. of about 15,000. P. being on one of the great

commercial tracks between Eastern Rajpootana and Sinde, much gain is made by the transit-trade.

POLYTRICHUM (Gr. many-haired), a genus of mosses, having the capsule supported on a stalk (*seta*) which is terminal, and thus appears as an elongation of the stem; the peristome single, of 32 or 64 short equidistant teeth, which are curved inwards, and their summits united by a horizontal membrane closing the mouth of the capsule. A number of species are found in Britain, of which the most abundant is *P. commune*, sometimes called *Hair-moss*, *Golden Maidenhair*, and provincially *Goldilocks*; growing in heaths and woods, particularly where the soil is sandy; the stems not at all branched, or only at the base, several inches long; the narrow slender leaves sometimes nearly half an inch long. This beautiful moss is very common in the most northern parts of Europe and Asia.

PONA'NI, or **PANIANI**, a seaport town of British India, in the district of Malabar, on the south side of an estuary of a river of the same name, about 600 miles south-east from Bombay. The river is navigable only for canoes to the distance of 63 miles from the sea. The population is employed in fishing and in trade, having numerous patamars, or sea-going boats. *P.* was formerly a much more considerable place, until nearly ruined by the oppression of Tipoo Sultan. Under the system of railways by which the Madras territories are about to be traversed, the eastern and western coasts of this part of the peninsula will be united by a line from *P.* to Madras. Pop. about 8000.

POPERINGHE, an old commercial town of Belgium, in the province of West Flanders, four miles from the French frontier. The town is walled, and has manufactures of lace, linens, and woollen cloths. Hops are grown in the surrounding district. Pop. (1863) 10,769.

PORDENO'NÉ, a town of Venetia, Italy, in the province of Udine, 40 miles north-north-east of Venice, on the Noncello, a branch of the Livenza. The town is situated in a pleasant plain, near the base of the Alps. It is a station on the railway between Venice and Trieste. The site is supposed to be that of the *Portus Naonis* of the Romans. There are several large paper-mills, also cotton and linen manufactures, oil-mills, manufactures of copper goods, and glass-works. Pop. 7383.

PORTER, **DAVID D.**, Rear-admiral of the American navy, son of Commodore David Porter, who commanded the *Essex* frigate in the war of 1812, was born in Philadelphia about 1805, entered the navy as midshipman in 1829, serving under Commodores Biddle and Pattison, passed his examination in 1835, was employed from 1836 to 1841 in the survey of the coast of the United States; in 1841, appointed as lieutenant to the frigate *Congress*, and employed four years on the Mediterranean and Brazil stations; in 1845, transferred to the National Observatory at Washington, and during the Mexican war, to the naval rendezvous at New Orleans; again to the coast-survey, and from 1849 to 1853, engaged in command of the California mail-steamers. At the commencement of the war of 1861, he was appointed, with the rank of commander, to the steam sloop-of-war *Powhatan*, and ordered to Pensacola; distinguished himself in the capture of New Orleans, and commanded the gun-boat and mortar flotilla which co-operated with the squadron of Admiral Farragut in the first attack upon Vicksburg. In 1863, he aided in the second and successful bombardment, and subsequently commanded the naval forces in James's River, and in the attacks upon Fort Fisher, captured at the second attack,

January 15, 1865; followed on February 19—22, by the capture of Fort Anderson and Wilmington. At the termination of the war, with the rank of rear-admiral, he was appointed Superintendent and President *ex officio* of the United States Naval Academy, Annapolis, Maryland.

PORTO-MAURIZIO, a seaport town of North Italy, capital of a new province of the same name, on the Gulf of Genoa, 58 miles directly south-west of Genoa city. Area of province, 467 sq. miles. Pop. (1861) 121,330. The town stands on a high promontory, projecting boldly into the sea, and has a lofty church, painted in brilliant colours. The harbour, defended by a mole, is generally crowded with the picturesque coasting-vessels of the Mediterranean. There is an extensive trade in olive-oil and agricultural produce. Pop. (1861) 6256.

POST-OFFICE INSURANCE is a valuable addition to the many useful services which our postal establishment has been enabled to render within the last few years. Book-post, sample-post, money-orders, and postal savings-banks, all additions to the original letter-post and newspaper-post, have been found to work so satisfactorily, that the legislature has been encouraged to intrust to the same organisation a new system of insuring lives and granting annuities—specially intended to foster provident habits among persons whose savings can be but small.

In 1853, an act of parliament made an improvement in the then existing state of insurance law, by facilitating the purchase of government annuities through the medium of the savings-banks; and in 1864, another statute gave a great extension to those portions of the system which had been found to work well, effecting at the same time alterations in those which had exhibited certain defects during eleven years' working. Great facilities are introduced by this act for securing annuities by small payments. Not only may the National Debt Commissioners employ the trustees of savings-banks to receive and pay the moneys, at a certain rate of remuneration; but the Postmaster-general joins in the arrangement, acting as a medium between the public on the one hand and the Commissioners on the other. Ample tables and regulations have been printed, for the guidance of the Commissioners, the Postmaster-general, and the local postmasters throughout the kingdom. On the completion of these tables and regulations in 1865, the practical working of the system began. The tables of the premiums to be charged for life-insurances, for immediate annuities, for deferred annuities, and for deferred monthly allowances, are sold by Messrs Eyre and Spottiswoode, the government printers, for 5*d.* (the cost of the paper and printing); but similar tables are kept for inspection at the local post-offices without charge.

In regard to insurance, distinct from annuities, persons of either sex may insure through the medium of the post-office. The limited ages are from 16 to 60, and the limited sums from £20 to £100. In order to afford every possible facility in the payment of the premium, minute calculations have been made of the exact sum to be paid at each instalment, by yearly, quarterly, monthly, or fortnightly payments, and terminable or not at a particular age. In order that there may be some limit to the labour thus placed on the postal authorities, no periodical instalment is made smaller than two shillings. No one life can be insured for less than £20 in the whole; but when a life has been insured for £20, further insurances may be effected on the same life from time to time, until the whole sum for which it is insured amounts to £100. The

Monte Video and Buenos Ayres, so that the overflowing plenty of those countries will be in time easily transferred to others not so favoured.

The eminent chemist Liebig suggested the manufacture of a concentrated extract of meat; and this is now carried on very extensively both at home and abroad. It is chiefly used by invalids, and for quickly making soups. Only the lean or muscular part is used, and this is boiled until all but the fibrin is dissolved out; the liquid is then concentrated until it is brought to the state of a thick paste, in which state it is easily preserved.

Another and most ingenious process has lately been patented, and is attracting much attention; it is called 'Redwood's Process.' This process, invented by Professor Redwood, consists in the immersion of fresh meat in melted paraffin, at a temperature of 240° F. (115° Centigrade), for a sufficient time to effect a concentration of the juices of the meat, and the complete expulsion of air; after which the meat, in its condensed state, is covered with an external coating of paraffin, by which air is excluded, and decomposition prevented. The paraffin used in the process is a perfectly innocuous substance; it is entirely free from taste and smell, and is not subject to change from keeping. It may be removed from the surface of the meat by putting the latter into a vessel containing boiling water, when the paraffin, as it melts, will rise to the surface of the water, and may be taken off in a solid cake when cold, while at the same time the meat will become softened and prepared for cooking in any suitable way. See SULPHUROUS ACID in SUPPLEMENT.

PREVEZA, or **PREVISA**, a town of European Turkey, in Albania, 20 miles south-west from Arta, and on the north shore of the strait which forms the mouth of the Gulf of Arta. Pop. about 8000.

PRIEGO, a town of Andalusia, Spain, in the province of Cordova, 45 miles south-east from the city of Cordova. The inhabitants of P. are chiefly occupied in husbandry. There are oil-mills, flour-mills, tanneries, and potteries. There were formerly very important silk manufactures, but these have become inconsiderable. Pop. (1860) 13,464.

PRILU'KI, a town of European Russia, in the government of Poltava, 138 miles north-west from Poltava. It has a considerable trade in corn, cattle, brandy, and saltpetre. Pop. (1863) 10,584.

PRINTING. In Printing, a remarkable American invention was brought into use in 1867. It is called the Matrix Compositor, and is only adapted for stereotyping, by making impressions on thick, soft paper of the letters in the order required, and then taking casts of the same in metal as usual. The peculiarity of this machine is, that it brings up any letter the compositor wishes to its right place in the line by simply touching the key which answers to that letter, in an arrangement like the front of a piano, each key being marked with its corresponding letter. At the moment the letter is brought to its place, it is made to press into the paper; and in this way the composition proceeds with only one alphabet of fixed types, which are made of steel to bear the pressure. With practice, a good compositor will work this machine, and thus form the matrix for the stereotype plates, as fast as he could set up the ordinary movable types. The saving in time and the wear of type is therefore very considerable.

PRIZZI, a town of Sicily, in the province of Palermo, and 30 miles south-by-east from Palermo. It is of considerable commercial importance. Pop. (1861) 11,138.

PROVISIONAL ORDER is an order granted under the powers conferred by an act of parliament, by a department of the government, by the Secretary of State, or by some other authority, whereby certain things are authorized to be done, which could be accomplished otherwise only by an act of parliament. The order does not receive effect, however, until it has been confirmed by the legislature. Till that time, it is purely provisional; and even after it has been so confirmed, and is in reality an independent act, it retains the title of a provisional order.

Provisional orders have been in operation in England for many years, and have been found most useful in facilitating the modification or extension of the provisions of general acts, so as to adapt them to the special necessities of particular districts. A general statute, dealing with an extensive subject like police or sanitary improvement, could only embrace provisions suited to the requirements of the country generally, and could not be so framed as to meet exceptional circumstances. When these had to be provided for, private legislation was necessary; but the cost and delay attendant upon the promotion of local acts in the usual way were so great as in many cases to be practically prohibitory. What was needed, therefore, was a ready and inexpensive mode of obtaining local legislation, and the system of provisional orders was devised to meet that want. The general act embodied legislation generally applicable, and gave power to some board or officer to issue provisional orders, whereby the general act might be better applied to special districts or under peculiar circumstances. Such powers were by the Public Health Act, 1848 (11 and 12 Vict. c. 63), conferred on the General Board of Health thereby constituted, but were by the Local Government Act, 1858 (21 and 22 Vict. c. 86), transferred to the Secretary of State. The Turnpike Trusts Act, 1851 (14 and 15 Vict. c. 38), empowered the same functionary to grant orders in reference to the objects of that act; while the Piers and Harbours Act, 1861 (24 and 25 Vict. c. 45), authorized the Board of Trade, with the sanction, in certain cases, of the Admiralty and Commissioners of Woods and Forests, to issue provisional orders dealing with a variety of important matters connected with the construction of piers and harbours, and the levying of dues and rates. The Lands Drainage Act, 1861 (24 and 25 Vict. c. 133), gave power to the Enclosure Commissioners to issue orders for the purposes specified in that act; and the Merchant Shipping Amendment Act, 1862, gave, relatively to its objects, corresponding powers to the Board of Trade.

All these acts were in full and beneficial operation in England when the General Police and Improvement (Scotland) Act, 1862 (25 and 26 Vict. c. 101), was passed, and it conferred extensive powers on the Secretary of State in relation to the granting of provisional orders for police and sanitary purposes. Subsequently, the Irish Drainage and Improvement of Lands Acts of 1863 and 1864 (26 and 27 Vict. c. 88, and 27 and 28 Vict. c. 72) enabled the Commissioners of Public Works, and the Oyster and Mussel Fisheries Act, 1866 (29 and 30 Vict. c. 85), enabled the Board of Trade, to issue orders in relation to the subjects of these acts respectively.

Nothing can be more diversified than the objects to be attained by provisional orders under the several acts above alluded to, and yet the course of procedure in relation to them all is substantially the same. A petition to the proper authority, specifying what is wanted, and supported by such evidence as can accompany the application, is made

the subject of inquiry by a qualified person commissioned for the purpose. After due inquiry has been made, and the result has been reported to the authority to which the application is addressed, the petition is disposed of, either by giving or refusing what is asked, or by giving it in a modified form. When a provisional order is granted, steps are taken on behalf of the government to have it confirmed by parliament. In the case of orders issued under the General Police and Improvement (Scotland) Act, for example, the requisite Confirmation Bill is framed, under instructions from the Secretary of State, by the Lord Advocate, who takes charge of the measure through its various stages. When unopposed in parliament, ten days or a fortnight usually suffice for the passing of the requisite Confirmatory Act, which has all the facilities of a government measure. Of course, the whole expense connected with the preparation and passing of the order, and the relative Confirmation Act, is defrayed by the applicants; but the advantages of provisional orders, compared with ordinary private bills, are nevertheless considerable. A provisional order may be got with greater expedition and at much less cost than a private bill. It is exempted from the tedious and costly formalities of complying with standing orders and making deposits, with all the formidable fees of the House, and other incidental charges. When opposition is offered, the opponents are fully heard by the commissioner appointed to make the requisite inquiries; and the grounds of opposition are deliberately weighed, first by him, and afterwards by the superior authority to whom he makes his report. The opponents have thus the satisfaction of knowing that their case has been considered, with probably the same result as if it had been submitted at much cost to a parliamentary committee. There is, therefore, little inducement in ordinary circumstances to appeal directly to the legislature; and, as a consequence probably, an opposition to a provisional order in parliament is exceedingly rare. No doubt, if an opposition on feasible grounds were offered to a provisional order in parliament, the whole subject would be referred to a select committee, who would probably proceed as in the case of an opposed private bill; but that, as has been observed, is of so rare occurrence, that it does not detract from what has been said in regard to the advantages of the system as a rule.

PRZEMYSL, a town of the Austrian Empire, in the province of Easter Galicia, on the right bank of the San, an affluent of the Vistula, 53 miles west from Lemberg. It is connected by railway with Cracow, and so with the west and north of Germany on the one hand, and with Lemberg on the other. P. is a flourishing town, carries on a considerable trade, and has manufactures of linens and leather. Pop. 9806.

PRZYBRAM, a town of the Austrian Empire, in Bohemia, 33 miles south-south-west from Prague, on the Litawka, a feeder of the Moldau. It derives its importance chiefly from extensive lead and silver mines in the neighbourhood, and is the seat of a superior court of mines. Pop. 7665.

PSEUDOSCOPE (*pseudos*, false, and *skopein*, to see), an optical instrument invented by Professor Wheatstone, and so called from the fact of its exhibiting objects, viewed through it, under aspects the exact converse of their natural appearance. Its construction is shewn by the annexed figure: *abc*, two rectangular prisms of flint-glass, the hypotenuses of which measure $1\frac{1}{2}$ inch in length, and $1\frac{1}{4}$ inch in depth. The prisms are hinged at *c*, so that they may be inclined towards each other in any desired degree, and are fixed each in a wooden

framework, fastened together by the hinge or pivot *d*. By means of the pivot *d*, the distance between *c* and *c* may be made to accommodate itself to the different interval between the eyes in various observers. In using the instrument, the eyes are placed at *E* and *E* respectively. The thumb-pieces attached to the prisms at *a* and *a*, are used in adjusting the instrument for distinct vision of any

particular object. The optical effect of each prism is twofold: it displaces the object, and it procures the lateral inversion of the image. From the latter circumstance, it follows that the right-hand side of a cube, for example, is seen on the left, and *vice versa*; this inversion being occasioned by the reflection of the rays upon the side of the hypotenuse within each prism. By the two refractions undergone by the rays as they enter and leave the prisms, the axis of the emergent pencil is no longer directed towards the real place of the object, but is diverted in such sort that the convergence of the optic axes *diminishes* as the distance of the object *diminishes*; and *increases* as its distance *increases*—a complete reversal of the ordinary conditions of sight, and one which, in conjunction with the lateral inversion before mentioned, gives rise to very curious visual phenomena. See **VISION**. It is essential to the efficient use of this instrument that the object be seen by both eyes; and therefore the observer, having placed the object at the usual distance for distinct vision, should, by closing the eyes alternately, ascertain that it is within the field of each prism. He should then adjust the prisms until the two images coincide in point of space, when they will coalesce, and, at first, the object will probably retain its natural aspect; but on a sudden, it undergoes a change, and the converse appearance stands out to view with the utmost distinctness and reality. A hat will appear to be turned completely inside out; the interior of a basin will appear convex and protruding; and 'a bust regarded in front becomes a deep hollow mask.' To facilitate the illusion, the object should be equally illuminated on either side, so as to prevent shadows.—For a full account, see the original paper by Wheatstone, *Phil. Trans.*, 1852, p. 11, *et seq.*

PUCCINIA, a genus of fungi, of the division *Coniomyces*, all very small and parasitic, on the leaves or stems of plants, within the tissue of which the mycelium creeps. One of the most common species, and the most important, is the **CORN MILDEW** (*P. graminis*), which is almost always present in corn-fields, and in some years is very injurious to wheat and other cereal crops. It is pitchy brown or black, and grows in irregular lines, somewhat following the venation of the leaf, the lines sometimes confluent. The spores are supposed to find their way from the root upwards, with the juices of the plant on which they vegetate, but this has not yet been proved by observation.

PUERTO-CABELLO, or **PORTO-CABELLO**, a town of Venezuela, in the province of Caracas, 78 miles west from Caracas. It stands on an island in the Golfo Triste, separated from the mainland by a channel so narrow as to be crossed

by a bridge. The situation is very unhealthy, but the harbour is safe and commodious, and a considerable trade is carried on. P. is the port of Valencia, which is rather more than 20 miles inland. Pop. 7500.

PULICAT, PALIKAT, or PALVELAKA'TU, a town of British India, in the presidency of Madras, and district of Chingleput, 20 miles north from Madras. It stands on an island in a large inlet of the sea or salt-water lake called the Lake of Pulicat. This lake is about 37 miles in length from north to south, and 11 miles in breadth at the widest. It contains a number of islands. The communication between the lake and the sea is by very narrow openings. The lake is much used as affording facilities of traffic by boats between Madras and more northern places. P. was occupied by the Dutch in 1609, and became afterwards the capital of their settlements on the Coromandel coast, but fell into the hands of the British in 1795.

PULWUL, a town of British India, in the district of Gurgaon, North-west Provinces, 36 miles south-by-east from Delhi, on the route to Muttra. Pop. 12,000.

PUNDERPU'R, or PANDHARPUR, a town of British India, in the district of Satara, and presidency of Bombay, 90 miles east from Satara, on the right bank of the Bima, a large branch of the Kistna. It is highly revered by the Hindus, on account of a celebrated temple dedicated to an incarnation of Vishnu. Pop. estimated at 20,000.

PUTEAUX, a town of France, in the dep. of Seine, at a distance of about two miles from the western boundary of Paris. It is situated on the left bank of the Seine, opposite to the Bois de Boulogne. The situation of P. is a very pleasant one, and many Parisians have fine villas here. The population and industrial activity of the place have of late greatly increased. Pop. (1866) 9375.

PUTTUN, PATTAN, or ANHULWAR PAT-TAN, a town of India, in the territory of the Guicowar, Guzerat, 64 miles north-west from Allahabad. It stands on the Saraswati, a small river, which is

a tributary of the Banas; and is a town of considerable importance, having manufactures of swords, spears, pottery of a light fine kind, and silk and cotton goods. P. occupies part of the site of the ancient city of Anhwara, the traces of the walls of which may still be seen, extending to about five miles in circuit. Pop. estimated at 30,000.

PYGMIES OF WESTERN AFRICA. The existence of pygmy races of human beings in Africa has been often asserted, and many circumstances less easily credible than their diminutive size have been reported. See **PYGMIES**. Du Chaillu has recently discovered the actual existence of a pygmy race, but of whom the diminutive size is the only remarkable characteristic. He found them in the mountainous country on the east of the southern great branch of the Ogobai. They are called Obongos, and live in the midst of negro tribes of ordinary stature. They shewed extreme timidity on being visited by a white man. In stature, they are only about four feet and a half. They subsist chiefly on animal food, but partly also on the roots, berries, and nuts which they find in the forests.

PYNE, LOUISA, a popular English singer, daughter of a well-known singer, Mr James Pyne, was born in 1832, received instruction from Sir George Smart, and first appeared in public in London in 1842. She appeared in Paris in 1847, made her *début* in opera in 1849, and has since visited America. She is chiefly known from her being chief soprano of an English opera company, in which she was associated with Mr Harrison at the Lyceum, Drury Lane, and Covent Garden.

PY'RITZ, a very ancient town of Prussian Pomerania, in the government of Stettin, 25 miles south-east of the town of Stettin. There are standing five high towers on the town-walls, built by the Wends, under whom it was a place of great strength. There is a seminary named after Otto, Bishop of Bamberg, near the spring where it is said he, in 1124, baptised the first Pomeranian converts. P. has manufactures of woollen cloth and leather. Pop. (1864) 7404.

Q

UANG-NAM, KUANG-NAM, or TURON, a town of Anam, about 75 miles south-east-by-east from Hué (q. v.), or Phu-thuan-thien, the capital of Anam. It is situated near the head of a beautiful gulf, and is a place of considerable trade.

QUE'DAH, KEDAH, KEDDAH, KEEDAH, or KIDAH, a half-independent state, on the west coast of the Malay Peninsula, on the Strait of Malacca.

It extends from about lat. 5° N. to lat. 7° N., and its average breadth is about 50 miles. The British province Wellesley, which lies between it and the sea-coast opposite to Penang, was separated from it and ceded to the British in 1800, by a treaty in which the British agreed to pay the rajah 10,000 dollars a year. Q. nominally owes a kind of feudal subjection to Siam, but is in reality much more subject to the sway of Britain.—The capital, from which the state takes its name, stands at the mouth

of a river also of the same name, in lat. 6° 6' N., and long. 100° 20' E. Its pop. is estimated at about 21,000.

QUEENS' COLLEGE, CAMBRIDGE, was founded in 1446 by Margaret of Anjou, consort of Henry VI., and refounded in 1465 by Elizabeth Woodville, consort of Edward IV. The college consists of a President and 14 foundation Fellows; the fellowships being tenable for ten years from M.A. without being subject to any restriction whatsoever; while any Fellow who takes holy orders, and has not a benefice of the net annual value of £300, may hold his fellowship for life. The new statutes provide that there shall be at least 14 scholarships, tenable till B.A., ranging between £30 and £50; the number and value of the scholarships to be augmented at the discretion of the President and Fellows. Besides these, there are 5 exhibitions, ranging from £12 to £20; and there are funds to the amount of £130 per annum at the disposal of the President, for the behoof of deserving

students of limited means. The College holds the patronage of ten benefices in the counties of Bucks, Cambridge, Essex, Leicester, Norfolk, Notts, and Wilts. Q. C. had, in 1865, 163 members of senate, 50 undergraduates, and 266 members on the boards.

QUEEN'S TOBACCO-PIPE, the facetious designation of a peculiarly shaped kiln, which is situated in the north-east corner of the Tobacco Warehouses belonging to the London Docks. These warehouses are rented by government at £14,000 annually. The kiln consists of a circular brick stalk, bulging out at the bottom to a width of five feet inside. A side-door of massive iron, lettered 'V. R., the Kiln,' gives access to the interior, in which are piled up damaged tobacco and cigars, and contraband goods, such as tobacco, cigars, tea, &c., which have been smuggled, books which are attempted evasions of the Copyright Act, &c., till a sufficient quantity has accumulated, when the whole is set fire to and consumed. The total value of the goods thus destroyed is enormous; and though this wanton destruction has often been censured, government still persists in the practice of periodically filling and lighting 'the Queen's Pipe.'

QUESALTENANGO, a town of Guatemala, Central America, the capital of a dep. of the same name. It is 66 miles west-by-north from Guatemala,

and stands in an elevated table-land, on a river which flows into the Pacific Ocean. After Guatemala itself, Q. is the most important town in the state. It manufactures cotton and woollen fabrics, and carries on a considerable trade. Pop. 25,000, mostly Indians.

QUILLOTA, a town of Chile, in the province of Valparaiso, and 22 miles north-east from Valparaiso, on the Aconcagua, about 20 miles from its mouth. Q. is a station on the railway from Valparaiso to Santiago, and is a place of some importance and some trade, the richest copper-mines of Chile being in its vicinity. To almost every house is attached a vineyard, but no wine is made. Pop. estimated at 10,000.

QUILO'N (*Kayan Kulan*), a town of British India, in Travancore, 35 miles north-west from Trivanderam. It is situated on the sea-coast, in a bight where ships may anchor and have shelter. Q. has a barrack for European troops, a hospital, a jail, &c. There is a considerable export trade in timber, cocoa-nuts, ginger, pepper, &c. The communication with Trivanderam is almost entirely by canals, connecting the lagoons of the *back-water*. There is similar water-communication with towns further northward on the coast. Pop. estimated about 20,000.

R

RACALMUTO, or **RAGALMUTO**, a town of Sicily, in the province of Girgenti, in an inland situation, on the crest of a hill 12 miles north-east from Girgenti. It is said to be of Saracenic origin. It has a castle, built by Frederick Chiaramonte in the 14th century. Pop. (1861) 10,397.

RACE, a term employed in some cases, particularly in the English Channel, to designate the powerful current formed by a rushing tide. Thus, between the island of Alderney and Cape La Hague, on the coast of France, is the *Race of Alderney*; and off the Isle of Portland, on the coast of Dorsetshire, England, is the *Race of Portland*.

RAG-TRADE. There is very little probability that the paper-manufacture will be permanently supplied with its main source of materials from any kind of fresh or green fibre (see **PAPER**). For the finer kinds of paper especially, rags of cotton and linen continue to be the main stay.

British paper-makers now require at least 120,000 tons of material yearly. In 1864, above 80,000 tons of this quantity were imported, and this ratio of two-thirds has since increased. It is not possible to say exactly how much of the rags and fibre imported are used for paper, seeing that much of the woollen rags is used for Shoddy (q. v.), and for manuring hops, broccoli, and other plants; while much of the fibre is used for certain kinds of textiles and cordage. The total imports in the above-named year were: 14,000 tons linen rags, 10,000 tons cotton rags, 16,000 tons woollen rags, 44,000 tons esparto and other grasses. In 1865, less linen and cotton, and more woollen and grass, were imported. It is a curious fact, that in China, where cotton garments are so largely worn, the rags, instead of being used

for paper, are pulped up into a material about an inch thick, which is used, when faced with a layer of leather, as soles for shoes. Most of the imported linen rags come from Germany and Italy, the former moderately clean, and the latter very dirty; therein revealing something of the habits of the people. Cotton rags and the waste from cotton-mills are gradually increasing in consumption for paper-making. Irish rags are dirtier than English, and town rags dirtier than those from country districts. Some of the foreign rags from Italy, Spain, Russia, and Egypt are in such a filthy state as to lessen their value considerably in the market. When the rags are too bad for any kind of paper-making, they are used to manure hop-grounds. The rags of challis (a textile material consisting of wool and cotton) are remarkably treated—the cotton is dissolved away by strong acid, and the wool used again as shoddy.

It is believed that the home supply of linen and cotton rags might be largely increased by greater care in housekeeping economy. Mr Herring, partner in a firm of paper-merchants, and author of several articles on this branch of industry, published, in 1860, a 'Letter,' addressed to clergymen and others, suggesting an organised plan for the attainment of this object. 'The general apprehension,' he remarks, 'that we require French or foreign rags for our manufactories, is a mistake; we have a sufficient supply at home if we will but make use of it. There are more rags wasted, burned, or left to rot, than would make our paper-manufacturers independent of all assistance from abroad.' His plan is, that every family should have a bag or bags for rags, which should be called for by local agents at stated intervals, and purchased at prices which would soon settle themselves in the market, and the agents would transmit the rags by rail to the paper-mills.

Better, certainly, than grubbing up rags from gutters and dust-heaps, to which they are too often consigned. The managers of ragged schools in London organised a *Rag-collecting Brigade* in 1862, consisting of poor boys whose business it is to collect waste rags and paper from houses and warehouses. Trucks are provided, and the boys are placed in uniform. Certain daily rounds are established, each truck being attended by one collector and two assistants. The attendants draw the truck; while the collector makes the purchases and pays the money. A tariff is established for each kind of rag and other waste; scales and weights are provided, and each transaction is entered in a book. A certain amount of cash is intrusted to each collector when he starts from the dépôt on his rounds, sufficient for the anticipated amount of dealings. Unless the beat be near the dépôt, one round generally suffices for each day.

RAMNAD, a town of British India, in the district of Madura, presidency of Madras, 125 miles north-east from Cape Comorin, and about five or six miles from the shore of Palk's Bay. In the centre of the fort is the palace or residence of the semindar, one of the greatest of his class in the south of India, his extensive possessions containing more than 2000 villages, and nearly 300,000 inhabitants. Pop. about 13,000, of whom 6000 dwell within the fort.

RANDA'ZZO, a town of Sicily, in the province of Catania, at the base of Mount Etna, and eight miles north-by-west from its summit, on the Cantara. It crowns the summit of a low cliff of lava, and ascends the slope above, with brown battlemented walls and Norman towers, so medieval in its whole appearance, that it has been likened to 'a town of the middle ages preserved as a curiosity.' R. is believed to have been founded by the Lombard adventurers who assisted Count Roger in his conquest of Sicily. Pop. (1861) 6727.

RA'NELAGH, a village forming part of the suburb of Dublin, is situated two miles south from the centre of the city. It consists of one principal street with a square, but is surrounded by villas. The pop. in 1861 was 3866.

RA'VENSBURO, a town in Württemberg, and capital of a bailiwick of the same name, in the Circle of the Danube, is pleasantly situated in a fertile and romantic valley, the Schussenthal, at the foot of a hill planted with vines. The principal industries are spinning wool and flax, weaving woollen fabrics, linen, and stockings, bleaching, making paper, playing-cards, furniture, wood-work, sawing wood, &c. Pop. 6817.

RECANATI, a town of Central Italy, in the province of Macerata, on the Musone, 14 miles south from Ancona. It is a station on the railway between Ancona and Rome. R. was a powerful military position in the 11th century: great privileges were bestowed on it by the Emperor Frederick II. in 1229, when the whole line of coast from the Potenza to the Musone was granted to it for the erection of a port. Pop. (1861) 6150.

REEVES, SIMS, an eminent tenor singer, born at Woolwich in 1821. Before attaining his fourteenth year, he was a clever performer on various instruments, and tolerably well versed in composition; and at that early age he was appointed organist and director of the choir in the church of North Cray in Kent. His musical education was conducted under J. B. Cramer, T. Cooke, and other artistes of note. He first appeared in public as a baritone at Newcastle in 1839. His *début* was a complete success; and he acquired fresh fame in Scotland and Ireland. In order to perfect his voice and style, he went to Paris, and after studying there for some time, appeared at Milan in the tenor part

of Edgardo in *Lucia di Lammermoor*, when his singing electrified the audience. He returned to England in 1847, and coming out at Drury Lane as Edgardo, was immediately recognised as the first living English tenor, and was engaged in 1848 at Her Majesty's Theatre. In 1851, he was equally successful as first tenor at the Italian Opera in Paris. He has sung much and with very great success in oratorio.

REFORM. The article **REFORM** in the *Encyclopædia*, closes with the withdrawal of Lord John Russell's bill in 1860. No one, remembering amidst what apathy that took place, would have expected, within so few years, to see the subject revive, and assume such large dimensions. Mr Gladstone's speech of 1864 first gave new life, and his declaration, that it lay with those who refused the elective franchise to justify the refusal, sounded the commencement of the new agitation. At the general election of 1865, reform was necessarily much discussed. The death of Lord Palmerston gave the country a ministry in which Lord Russell led the House of Lords, and Mr Gladstone led the House of Commons. This ministry was not long in attacking the subject, and the reform discussions of 1866, so valuable as preparing for the final settlement of the question, commenced. The ministry adopted a suggestion which Mr Bright had made, and tabled first a bill dealing with the franchise alone. Its proposals were of a moderate enough description, its leading provisions being to give the franchise to occupiers of premises of the annual value of £7 in boroughs, and of £14 in counties. At the desire of the opposition, led by Mr Disraeli and Lord Stanley, government introduced its Redistribution of Seats Bill, and the two bills were combined and sent to committee together. In committee, parliament proved unmanageable. Several clauses were carried by the narrowest majorities, till at length, on the comparatively small question, whether 'clear' or 'rateable' annual value should be taken as the basis of the franchise, government was left in a minority of seven. The leaders, true to the traditions of party, resigned, and left the question of reform to the Conservatives.

The resignation was beneficial to progress. In the autumn following it, numerous mass meetings, conducted in general with perfect order, were held; and some unlucky speeches of the opponents of any reduction of the franchise were employed more or less unfairly in order to get a starting-point for the kind of eloquence that such meetings require. It now became plain that the main drawback to reform, the alleged indifference of the working classes, had ceased to exist. Reform therefore became inevitable; and it was equally clear that if reform was to be carried by the Conservatives, the country would not accept from them a measure of the moderate character which it would have gladly taken from the Liberals shortly before.

The meeting of parliament in 1867, it is said, found the ministry of Lord Derby and Mr Disraeli still undecided. But it was necessary to do something. The Queen's Speech accordingly broached the matter; and in the beginning of the session, Mr Disraeli proposed to deal with the subject by way of resolution. His resolutions, however, were vague, and had to be withdrawn. Mr Disraeli then (25th February 1867) made a speech, in which he proposed to bring in a bill, with a £6 rating franchise in boroughs, a £20 rating in counties, and with some of what were called 'fancy' franchises. With the redistribution question, he proposed to deal much as his actual bill afterwards dealt. This proposed bill was understood to be a compromise with a section of the cabinet not

REFORM.

favourably disposed to reform. However, as it did not succeed in making matters smooth, the leaders of the government are said to have reverted to what was their original policy. The dissentients, Lord Carnarvon, Lord Cranborne, and General Peel, then resigned, and (on 18th March) the Reform Bill of 1867 was introduced.

The bill surprised the country. Mr Disraeli has since said that, so far back as 1859, he and Lord Derby came to the conclusion, that if the £10 line, at which the Reform Act of 1832 had fixed the borough franchise, were disturbed, there was no other fixed line tenable; and he has made the further revelation, that he spent the interval between 1859 and 1867 in educating his party to the belief, that if the borough franchise was to be dealt with at all, it must be dealt with in the boldest manner. His bill, therefore, carrying out this policy, proposed that all householders within borough who were rated for the payment of poor-rates, should be entitled to vote. There were certain 'securities' attached to this proposal. The householder must have resided two years in the borough, and must have personally paid his rates. Further, the 'fancy franchise,' which again made their appearance, had coupled with them what was called the 'dual vote,' the object of which was to give to every householder who possessed one of them a second vote in addition to the first, which his house would give him. In counties, the bill proposed a £15 rating franchise, and all existing franchises were permitted to remain. In redistribution of seats, the bill proposed to take the second member from each borough of less than 7000 inhabitants, and to divide these seats, together with the seats taken from the corrupt boroughs, in nearly equal proportions between the larger counties and boroughs, giving one also to London University.

The bill was not permitted to pass without many alterations. Government, either influenced by a sincere desire for reform, or convinced that, as reform was at anyrate unavoidable, it was better that it should pass under their management than under the management of their opponents, were quite resolved that a bill should pass. They yielded to the House whenever they well could, and when they could not, the threat of dissolution at once brought the House to reason. The result of the labours of the session admits of being shortly stated.

The borough franchise remained substantially as at first proposed. Much of the session was lost in devising clauses by which the rating principle could be applied to those tenants whose landlords compounded for their rates. The principle was, however, maintained; and an amendment introduced by Mr Gladstone, with a view of fixing the hard and fast line of £5, was rejected. But by a new clause, the system of compounding was put an end to, so that the franchise was really given to all householders except those excused from rating on the score of poverty. The period of residence, on the motion of Mr Ayrton, was reduced from two years to one. On the motion of Mr M'Cullagh Torrens, an important addition was made in the shape of the lodger franchise. Mr Disraeli's bill of 1859 had contained a provision of the kind, and something like it was again added. It gives votes to all lodgers who have occupied for a year lodgings which would let unfurnished for £10, and who apply to be put on the roll.

The county franchise was reduced from £15 to £12 rating; and there was added (on Mr Colville's motion) a reduction of the copyhold and leasehold franchise, giving votes to all owners or liferenters of the free annual value of £5 in property other than freehold, which continues to yield a 40s. franchise.

The dual vote was early abandoned, and its abandonment involved that of the 'fancy' franchises. These have now only interest as matters of history; but as the name appears often in the discussions, it should be mentioned that, in their last form, they proposed to give votes to all who paid £1 annually in direct taxes (not including licenses), who belonged to certain of the better educated professions, or who had £50 in a savings-bank or in the funds. Mr Mill's proposal to extend the franchise to women found 73 supporters. The vote by ballot was rejected, equally with the government proposal to take the vote by means of voting-papers.

The comparatively restricted proposals of the government with regard to redistribution of seats were considerably extended. On Mr Laing's amendment, the limit at which boroughs then returning two members should hereafter return only one, was raised from 7000 inhabitants to 10,000. This gave 38 seats to be distributed,* making, with the 7 seats forfeited for bribery by the boroughs of Lancaster, Yarmouth, Reigate, and Totness, 45 in all. Of these, 25 were given to the larger counties, which were severally divided into two or more districts for the purpose.† To boroughs, 19 new members were given—8 by way of additional members to boroughs already possessing members, and 11 to new boroughs.‡ To the University of London, one member was given. Mr Laing's proposal to make the scheme of redistribution still more extensive, by applying to all boroughs having fewer than 5000 inhabitants the system of grouping which prevails in Wales and Scotland, was rejected.

The only amendment of importance which the House of Lords succeeded in making, was the addition of the system of representation of minorities. By this system, persons voting in London, where four members are returned, cannot vote for more than three; and in the counties and boroughs which return three members, cannot vote for more than two. The object is to prevent a majority which may possibly exceed the minority by only one man, from monopolising the whole representation. The plan appeared first in Lord John Russell's bill of 1854, and having then been unpopular with both sides, does not appear to have been proposed since. Mr Disraeli took occasion, in introducing his bill, to declare himself against it. Mr Lowe proposed to

* The boroughs from which one member each was taken were Andover, Bodmin, Bridgenorth, Bridport, Buckingham, Chichester, Chippenham, Chipping-Wycombe, Cirencester, Cockermouth, Devizes, Dorchester, Evesham, Great Marlow, Guildford, Harwich, Hertford, Honiton, Huntingdon, Knaresborough, Leominster, Lewes, Lichfield, Ludlow, Lynton, Maldon, Marlborough, New Malton, Newport (Isle of Wight), Poole, Richmond, Ripon, Stamford, Tavistock, Tewkesbury, Thetford, Wells, and Windsor.

† West Kent, North Lancashire, East Surrey (already having two members each), and South Lancashire (already with three members), were subdivided, and two members given to each division, which absorbed 7 seats; and the counties of Chester, Derby, Devon, Essex, Lincoln, Norfolk, Somerset, and Stafford, together with the West Riding (all already in two divisions, with two members each), were divided into three parts, each represented by two members, which absorbed the other 18 seats.

‡ Birmingham, Leeds, Liverpool, Manchester, Merthyr-Tydvil, and Salford got each an additional member. The Tower Hamlets were subdivided, and got two additional members. Chelsea was made a borough, returning two members; and the following boroughs were appointed to return one each: Burnley, Darlington, Dewsbury, Gravesend, the Hartlepool, Middlesborough, Staleybridge, Stockton, and Wednesbury.

REFORM—REFRIGERATING MACHINES.

add it in the Commons; and his proposal was supported by such men as Lord Cranborne among the Conservatives, and Mr Mill and Mr Fawcett among the Liberals. Mr Bright joined the government in opposing it, and it was lost by a majority of 141. In the House of Lords, its insertion was again proposed by Lord Cairns, and carried by a very large majority, most of the Conservatives voting for it, against the government. When the Lords' Amendments were considered in the Commons, it was the only one of them which was agreed to. It is hardly necessary to say that a scheme such as that of Mr Hare, for carrying out the principle in a rigorous and complete manner, was found to be far in advance of the day.

The opportunity of passing the Reform Bill was taken to provide for some minor improvements. The inconvenience of having parliament dissolved by the demise of the crown was obviated, and it was provided that ministers of the crown and their subordinates changing from one office to another should not have to submit to re-election. A boundary commission was appointed to re-adjust the boundaries of the boroughs and counties. Mr Fawcett's proposal to throw the necessary expenses of elections, such as the expenses of polling-places, sheriffs, &c., on the borough or county rates, was, however, rejected.

Such is the Reform Act (for England) of 1867. Its passing, in some shape or other, from the temper of the government and its power of controlling the House, was at no time in serious risk. The most critical period was when Mr Coleridge's amendment was brought forward, with the view of making way for Mr Gladstone's amendment of the £5 rating limit; and here the government were served by the defection from the Liberals of 'the tea-room' party—a large number of 'extreme' and 'independent' Liberals, some of whom really preferred the quasi household suffrage scheme of the government, and others of whom were only resolved that a bill of some kind should pass. Mr Gladstone's amendment was thus defeated.

Acts similar to the English one were passed for Scotland and Ireland in the session of 1868. The borough franchise for Scotland is substantially the same as for England, being conferred on every man who has for twelve months occupied, as owner or tenant, any dwelling within the borough, except he has been exempted from poor-rates on the ground of inability to pay, or has failed to pay. Scotland has also the £10 lodger franchise. In Scottish counties, proprietorship to the extent of £5 of clear yearly value confers a vote; the limit of the tenant franchise is £14. The Scottish act disfranchised seven English boroughs, and gave seven additional representatives to Scotland—two of these being assigned to the universities, and the rest to the larger towns and counties. The universities of Edinburgh and of St Andrews return one member jointly; as do those of Glasgow and Aberdeen. The Irish act made no alteration in the county franchise, but reduced that of boroughs to a £4 rating occupation.

As thus chosen, the House of Commons was composed, in 1869, of the following representatives:

| | Of Counties. | Cities and Boroughs. | Universities. | Total. |
|--------------------|--------------|----------------------|---------------|--------|
| England and Wales, | 187 | 301 | 5 | 493 |
| Scotland, | 32 | 26 | 2 | 60 |
| Ireland, | 64 | 39 | 2 | 105 |
| United Kingdom, | 283 | 366 | 9 | 658 |

REFRIGERATING MACHINES. Under the head ICE, some notice is given of machines by which it can be prepared artificially; but as the practical importance of refrigerating apparatus is daily increasing, we propose to give here a fuller

sketch of one or two kinds. The ice-making machine of Carré & Co. of Paris, being one of the simplest and best of those which produce cold by the evaporation of some volatile liquid, we shall describe it first. It is shewn in figures 1 and 2, and consists of two strong cast-iron cylinders A and B, connected together by a metal tube T, all perfectly gas-tight. The whole apparatus is made strong enough to stand seven or eight atmospheres of internal pressure.

The cylinder A is charged with a concentrated aqueous solution of ammoniacal gas. Ammonia is a powerful absorber of heat, and is, moreover, so extremely soluble in water that the latter takes up nearly 700 times its volume of the gas. Air is completely expelled from the apparatus by opening a screw valve and heating the cylinder. It is then ready for use. On applying heat to the cylinder A (fig. 1), which fits into a small stove for the purpose,

Fig. 1.

the solution of ammonia is volatilised, and carried over and condensed in the cylinder B, which is placed in a vessel containing cold water. The heat reaches to about 220° F., and while it is being applied, the volatilised ammonia condenses into a liquid under very high pressure, produced by its own atmosphere, in the cold cylinder B. When the heating has gone on long enough—about half-an-hour for a small machine—the hot cylinder, A, is removed from the fire, and placed in a vessel of cold water, as shewn in fig. 2. The cooling of this

Fig. 2.

cylinder immediately causes the reabsorption, by the removal of the pressure, of the condensed ammonia from the other cylinder B; and as it

REFRIGERATING MACHINES.

passes again from the liquid to the gaseous state, intense cold is produced (see HEAT), and, in consequence, heat abstracted from everything in contact with this portion of the apparatus.

The cold cylinder B is shewn in section in fig. 2. It is so constructed that the ammonia is contained in an outer jacket, leaving a hollow space in the centre. When ice is to be made, the latter is filled with salt water or other liquid which does not freeze at 32° F., and into this is placed a loosely fitting metal cylinder D, containing the water to be frozen. In this way, with a small machine for domestic purposes, a few pounds of ice can be made in an hour or two; but large machines, on the same principle, are made which produce 440 lbs. of ice per hour.

An Italian, named Toselli, has recently brought out a modification of Carré's machine, in which the ammonia is volatilised by hot water instead of by a stove. This is considered to be a practically safer and more convenient plan.

There is another excellent refrigerating machine constructed by Mr D. Siebe of London, where ether is used as the volatile fluid instead of ammonia. It operates on essentially the same principle; but a powerful pump, worked by a steam-engine, is used to facilitate the evaporation of the ether. Some machines are also in use which produce

Works, undertook, a few years ago, a series of experiments with a view to the construction of such an apparatus which would produce cold by the simple expansion and compression of air. He ultimately succeeded in producing a most efficient machine, which he patented on the 25th April 1862, the number of the specification being 1218.

Although it is not strictly true that the mere rarefaction of air produces cold, yet it will simplify the explanation of this machine to assume in the meantime that it does so. Its simplest form is shewn in fig. 3, and consists of a cylinder with a piston to compress air, communicating with another cylinder containing a kind of piston or plunger where the compressed air is cooled and expanded. The machine is driven by a steam-engine, and it may be as well to remark, that the actual relative position of the cylinders is different from that shewn in the diagram, which is given rather to shew the principle of the apparatus than as an accurate representation of it.

The compressed air is forced by the compressing cylinder A, into the refrigerating cylinder BB, just at the moment when the position of the plunger, PP, is close upon the upper cone D. This air, which fills the space *aa*, between the plunger, PP, and the lower cone E, is of course heated by the compression; and in order to cool it again, cold water is made to circulate in the cone E, by an entrance-pipe F, and an exit-pipe at G. The next movement of the machine draws the piston in the cylinder A to the opposite end, and consequently allows the compressed air to expand again; but at the same moment the plunger, PP, descends close upon the cone E, thus allowing the space between the plunger and the upper cone D, to be at its fullest when the expansion of the enclosed air is at its greatest.

By this arrangement, the patentee secures that the air while being compressed will always be at the lower, or what he calls the hot end, of the refrigerating cylinder B; and while being expanded, it will always be at the upper or cold end. There is a regenerator constructed as in the Caloric Engine (q. v.) of wire-gauze, placed in the middle of the plunger at C. This, while it allows the air to move freely through it, prevents the conveyance of heat or cold from one end of the cylinder to the other. The plunger, PP, is filled internally with sawdust or some non-conducting material.

We may now explain that the low temperature of the air which surrounds the cone D during expansion, is not produced by simple rarefaction. That alone would not produce cold. It is necessary as well to abstract heat from the air by giving it some work to do, and here it unavoidably does work, in assisting to force back the piston of the compressing cylinder, while in the act of expanding. The air loses an equivalent of heat exactly in proportion to the amount of force which it expends in moving, or in assisting to move, the piston. See FORCE.

Before air is admitted into the cylinders, it is necessary to dry it thoroughly, by first passing it through a box containing chloride of calcium, because, if any moisture were present, it would freeze in the regenerator, and stop the action of the machine. In the particular form of the apparatus shewn in the figure, the substance to be cooled is placed inside the cone D, which is furnished with a lid L. Here not only water, but even mercury, can be frozen with facility.

Most of the machines of this kind which have as yet been made were required for working on a more extensive scale than the one shewn in fig. 3 could easily do. In the larger-sized machines, accordingly, instead of one hollow cone like D

Fig. 3.

ice by means of freezing mixtures; but they are of minor importance.

Mr A. C. Kirk, late of the Bathgate Chemical

(fig. 3), a series of circular V-shaped corrugations are fixed to the top cover of the refrigerating cylinder, as shewn in fig. 4. These form annular passages, through which a continuous current of

Fig. 4.

some fluid not easily frozen, such as brine, flows. This is of course cooled by the expanded air (in the manner already explained), at the cold end of the cylinder, and can be conveyed away in pipes to cool any substance at a greater or less distance from the machine.

The first machine which Mr Kirk made was designed for the purpose of freezing out the solid paraffin from paraffin oil, and the work actually done by it was found to be equivalent to the production of two tons of ice in 24 hours, one indicated horse-power being consumed for every 212 lbs. of ice made. It was not, however, constructed to work at a greater maximum pressure than 70 lbs. per square inch. One made to work with double this pressure would produce four tons of ice per day, while the cost of it would not be materially increased.

It is only within the last ten years that much attention has been given to the construction of machines for the production of artificial cold on the large scale, but there can be little doubt that they will now receive many important applications. There is no difficulty in working with one on Kirk's principle anywhere, because it can be so constructed that even a pair of bellows will compress the air enough. In this country, besides being available for the production of ice; the extraction of certain salts from mixed solutions, such as sulphate of soda from common salt—the former separating at a temperature above that which keeps the latter in solution; the separation of paraffin from mineral oils; and in other chemical operations, as well as for cooling worts in breweries and distilleries, they can also be turned to good account in the salting and preservation of meat. In warmer countries, they will be still more useful, and perhaps most of all in cooling large hospitals and public buildings, by sending a current of some cold liquid through pipes, just as we in Great Britain heat

such buildings with pipes through which hot water is made to flow.

RE'NI, a town of Moldavia, at the confluence of the Pruth and the Danube, on the left bank of both rivers. It carries on a considerable trade, exporting large quantities of grain. Pop. about 8000.

RETIMO, a seaport town of the island of Crete, on its north coast, 35 miles west from Candia. The neighbourhood is productive both of oil and wine. Pop. (1863) 7800, of whom 5800 are Turks, and 2000 Greeks.

REVI'VALS OF RELIGION. The term *Revival of Religion*, or, more briefly, *Revival*, is employed to denote an increase of faith and piety in individual Christians, particularly after a period of religious declension, and also an increase of religion in a community or neighbourhood, both through the revival of those who are already religious, and through the conversion of the previously irreligious. In these applications, its use is countenanced by several passages of Scripture; the idea which it is intended to convey is, however, far more frequently suggested by passages in which the term does not occur. The idea of revival is more particularly connected with the system of 'evangelical' doctrine, and particularly with that part of it which relates to the work of the Holy Spirit in the conversion of sinners.

What are commonly called revivals of religion may be described as religious movements or excitements extending, more or less generally, over a neighbourhood, or sometimes over a country. By those who regard them as genuine, it is urged in their favour, that they are in accordance with what the Scriptures teach us to expect, and that we have instances of a similar kind recorded in the Scriptures themselves—both in the history of the Jews, and in the early history of the Christian Church, particularly in the effusion of the Holy Spirit on the day of Pentecost, and afterwards in connection with the ministry of the apostles, when many were converted through a single discourse, or, in other cases, evidently within a short time. It is further urged that the promise of the effusion of the Spirit in 'the latter days' was not completely fulfilled on the day of Pentecost, but relates to the whole period of the Christian dispensation, and that, according to many prophecies, we have reason to expect even more of it in future times than there has ever hitherto been, so that 'a nation shall be born in a day, and the kingdoms shall be the Lord's.' The Reformation of the 16th c., and the more partial movements of the same kind which preceded it, are also regarded as essentially revivals of religion—the Reformation itself the greatest which has taken place since the apostolic age. The great development of religious fervour in England in the 17th c., is, according to this view, to be considered as a revival, and the extravagances which attended it as mere excrescences, like those of the Anabaptists in the time of the Reformation. The next great movement of the same kind was that in the first half of the 18th c., from which the Methodist churches originated (see METHODISTS). It was accompanied with many circumstances similar to those which have attended later revivals of religion. The term revival did not begin to be commonly employed till after this period; and the revival which took place in New England and other parts of North America about the same time, was then and still is generally designated the *Great Awakening*. The beginning of this revival seems to have had no connection with the Methodist movement in England, although subsequently

REVIVALS OF RELIGION.

they became connected through Mr Whitefield's visits to North America. The revival in New England, which began about 1734, under the ministry of the celebrated Jonathan Edwards at Northampton, and rapidly extended over great part of New England and New York, was speedily followed by similar religious movements in Scotland, not altogether independent of it. Such religious movements had not, however, been unknown in Scotland before, although very much confined to particular times and localities. In 1625 and some following years, there was a revival at Irvine, under the ministry of Mr David Dickson—a minister of more than ordinary abilities and attainments, some of whose works have recently been republished—so considerable as to be noticed in many histories of the church of Scotland, and which, because it extended very much to the neighbouring parish of Stewarton, and along the banks of the Stewarton Water—the people of that district frequenting Irvine on market-days, and hearing Mr Dickson's lectures—was contemptuously styled by its adversaries the *Stewarton sickness*. In 1630, several hundreds are said to have been converted at once, through a sermon preached at Kirk-of-Shotts by Mr John Livingstone, then a young preacher, but afterwards an eminent minister of the church of Scotland, and a sufferer for the cause of Presbyterianism. About the same time (1623—1641), similar movements took place in Ireland under the ministry of Scottish Presbyterian ministers settled in Ulster, and to which the origin of the Irish Presbyterian Church must in great part be ascribed. The Presbyterians of Scotland were thus in some measure prepared to acknowledge the revivals of the earlier part of the 18th c. as genuine, which began at Cambuslang—Mr McCulloch being minister of that parish—in 1742, and speedily extended to Kilsyth and other parishes in the neighbourhood, as well as to Dundee and other places more remote. No similar movement, however, took place over the country generally; nor was there anything of the same kind again till the very end of the century, when a revival took place (1798—1800) at Moulin in Perthshire, of which Mr Alexander Stewart was then minister. This was followed in a few years by a revival in Arran (1804—1813), under the ministry of Mr M'Bride. Other similar local revivals followed, not unfrequently, and in parts of Scotland widely remote from each other, both in the Highlands and Lowlands; and also in other parts of Britain, particularly a very extensive one in Wales, resulting in the formation of the Welsh Calvinistic Methodist Church, but not confined in its effects to those who became connected with that church. Local revivals also in some instances attended the ministry of evangelical ministers of the Church of England.

In 1839, the attention of all Scotland was drawn to a religious movement at Kilsyth, which was followed by similar occurrences in a number of other places, more or less evidently connected with it. The first appearance of an unusual degree of religious feeling at Kilsyth was in the parish church, during a sermon by Mr William C. Burns, a son of the minister of the parish, and now a missionary in China. The emotion of many of the congregation broke out in sobs and cries, so that for a time the preacher's voice could scarcely be heard. For months, religion was the almost exclusive subject of interest to a great part of the inhabitants of the parish, and many meetings for public worship were held besides the ordinary Sabbath services, at which great emotion was often displayed. Among the other places to which this movement notably extended was Dundee, where Mr W. C. Burns was then stately employed in the ministry of the

gospel. After 1839, there were revivals from time to time in various places in Scotland; but none of great extent or interest there or elsewhere in the British Islands for nearly twenty years. There had, meanwhile, been many revivals in America, generally, indeed, confined to particular congregations, seminaries, or localities, but sometimes extending over considerable districts; and throughout at least the northern and middle parts of the United States, the idea had become familiar to the popular mind, that revivals of religion ought to be expected from time to time; from which naturally followed the belief that means ought to be employed to produce them. From this resulted, in some cases, increased earnestness in preaching and prayer, with greater assiduity in the use of all the ordinary means for the promotion of religion; in other cases, direct endeavours to produce excitement, as by *camp-meetings*—assemblies of great numbers of people held in the open air, and at which exciting addresses were delivered by preacher after preacher, to work upon the nervous sensibilities of the audience.

Nothing of this kind, however, attended the commencement of the great religious movement which took place in 1857 and in the two following years. Its origin is ascribed in part to the thoughts and feelings awakened during a period of great commercial distress. It began in New England, particularly in Connecticut and Massachusetts, and rapidly extended to New York and over the middle and western states. It was not generally attended with scenes of great excitement. Strong, but calm religious feeling was its general characteristic. In the city of New York, almost every congregation received a great accession of members, and prayer-meetings were held for about an hour in the middle of the day, which were attended by great numbers of persons actively engaged in business. More than 2000 places in the state of New York were reported as partaking of this revival. Not long after it began in America, a similar movement took place in the north of Ireland, not apparently connected in its origin with that in America, although certainly connected with it soon afterwards, and promoted by the news brought across the Atlantic. It is said to have begun in a prayer-meeting at Connor, in the end of 1857, and rapidly extended over the whole north of Ireland, and subsequently to many parts of Scotland, Wales, and some parts of England. In some places, it was attended with much excitement and various forms of extravagance; more generally, it was characterised by little else than the intensity of religious feeling displayed.

Revivals of religion have occurred also in other parts of the world. About forty years ago, a widespread movement of this kind took place in Switzerland, although not affecting more than a small part of the population anywhere. Under the ministry of Felix Neff, it subsequently extended to the Protestant districts of Dauphiné, and to the neighbouring Vaudois or Waldenses, on the Italian side of the Alps. More recently, but throughout many years, similar religious movements have occurred in Sweden, in many different parts of the kingdom.

Revivals have been accounted for in very different ways; but in general, too evidently in mere accordance with the different religious views of those by whom the theories have been proposed. Some have attempted to explain the phenomena of religious excitement extending over wide districts, and rapidly spreading from one place to another, by the supposition of a kind of epidemic disease affecting the mind. Another opinion very valently entertained by those who do not see in revivals anything really good, is, that they are

REVIVALS OF RELIGION.

the result of endeavours to work upon the feelings. It is replied, that although this theory might be plausibly enough advanced, if only such things were considered as the camp-meetings of the American Methodists, it is far from being in accordance with the best ascertained facts as to many of the revivals which have taken place both in America and in other countries. It is certain that many of these have taken place without any apparent attempt to work upon the feelings, more than is ordinary and proper in the preaching of the gospel, and that the greatest display of emotion has often been connected with preaching of the most simple and sober kind.—By those who believe in the reality of revivals, as productive of a true increase of religion, they are generally ascribed to the operation of the Holy Spirit, to which, according to the 'evangelical' scheme, the 'conversion' of every individual soul is ascribed, and also all increase of faith and piety in the converted. Revivals have, however, often been regarded with doubt by many who believe in the whole doctrine of the work of the Spirit as generally held in the Protestant churches, but who look upon the excitement frequently attending them as inconsistent with the proper sobriety and solemnity of religion, and think the progress of religion ought rather to be expected to be gradual, and without very much to call particular attention to it at one time more than another. It is replied, that whilst a blessing on the regular use of ordinances may confidently be expected, if duly sought by prayer, there is yet much in Scripture to favour the notion that particular seasons may be unusually marked by the evidence of it; and further, that revivals, when they take place, generally shew the usefulness of the ordinary means employed for the promotion of religion, as they seldom occur among persons very ignorant of religion, but rather among those who have previously enjoyed the benefit of the most faithful ministrations. With regard to the excitement attending many revivals, it is argued that this excitement is not wonderful, if persons are suddenly impressed with a deep sense of their sins, of the danger of divine wrath, and of the importance of religion; and that it is in some measure also to be expected in those who are brought by a quick transition from deep distress to a full sense of forgiveness and the favour of God. Are we to be surprised, it is asked, if persons in such circumstances, after much effort of self-restraint, cry aloud in the congregation, or fall down, overpowered by their emotions? It is sometimes alleged by the opponents of revivals, as an objection to them, that much of the excitement manifested in them is merely hysterical; and some of their advocates have rashly denied that this is the case; others, admitting it, deny that it affords any just cause of objection, and maintain that hysterical excitement is natural and unavoidable in such circumstances, and however undesirable in itself, is a manifestation of the reality and strength of the feelings awakened. They acknowledge, however, also, that like similar excitement produced by causes which have nothing to do with religion, it may extend from one to another, even where the cause in which it originated does not operate; and they therefore refuse to see in it, considered by itself, any evidence of the religious or spiritual condition of the persons affected by it.

That much folly and extravagance have often been exhibited in connection with revivals of religion, is freely admitted by many who are fully convinced of their reality; but this, they say, is also only what might be expected, as the occasion always seems a favourable and inviting one to persons whose zeal exceeds their discretion, and too often affords

opportunity for ignorant and self-conceited persons to thrust themselves forward as teachers and conductors of religious exercises.

It may be proper to advert to some of the practices which sometimes take place on occasions of revival, but which are disapproved by all except those who are filled with the desire of seeing excitement produced and increased. Among these is the bringing forward of persons in the character of new converts, to conduct prayer in public, and to address meetings, which they are often among the least capable of doing well. Another practice liable to much objection is the permitting of mere youths, under profession of Christian zeal, to converse in private with persons in distress of mind, especially when these are young persons of the other sex. A third objectionable practice is the calling upon those who are anxious about their salvation to come forward and occupy a place by themselves—or what are called in America *anxious seats*—that they may be individually conversed with, and that special prayer may be made for them, they being thus brought into a publicity which is undesirable. It is hardly necessary to refer to the absurdity of demanding—as has sometimes been done—a show of hands from those who are now resolved to give themselves to the Lord! With such uncommendable practices may be classed that of encouraging persons who have been of very profligate life to recount their own history, which has sometimes been carried so far, that they have seemed even to glory in the enormity of their past wickedness.

Certain peculiar modes of expression, which might not unaptly be designated a kind of slang, have often come into use in connection with revivals of religion, with the unhappy effect of exciting disgust in many minds, and particularly among the most educated classes of society. Thus, in the revival of last century in New England, the subjects of the revival—in a certain state of their experience—were spoken of as being *filled*. In the recent revival in Ireland, it was common to speak of those who fell down suddenly in congregations or in their own houses as *stricken*, and as the *stricken ones*. It was very common during the same revival to speak of individuals as having *found peace*; and this finding of peace was by some regarded as proof of conversion, or even as indicating the moment of conversion—all which was considered by many who fully believed in the reality of the revival, as unscriptural and delusive.

Among the evils acknowledged to attend revivals by those who believe them to be real, but who also believe that there is often much connected with them which is not the work of God, is the disposition to judge of the spiritual state of individuals, as converted or unconverted. *New converts*, especially when brought into undue prominence, are apt to become elated and self-satisfied, and even to regard themselves as the only true Christians, or as superior to those whose piety is of much longer standing than their own. This, however, is not always the case, and much depends on the judicious or injudicious conduct of the ministers chiefly concerned when a revival takes place.

We have endeavoured to present this subject fairly to our readers; but it is evident that as to the opinion to be formed by any one, much must depend upon the general religious views which he entertains. As to mere religious excitement, however, and bodily affections resulting from it, many facts may be adduced to shew, what might be supposed beforehand, that these may be connected with religious views extremely at variance. Excitement may be produced by religious views that are utterly false, as well as by those which are true. Heathenism

has always abounded in it; Mohammedanism has much of it; and it has appeared in the church of Rome as well as in the Protestant churches. It is not necessary to do more than allude to the extravagances of the Flagellants, and to the strange scenes of the Dancing Mania. Some of the small sects, also, which evangelical Protestants regard as most heterodox, seem to maintain their existence by a systematic working up of excitement.

The subject of this article has been treated in a multitude of publications, almost every revival which takes place calling forth new pamphlets, narrative and controversial. The works of Jonathan Edwards deserve the first attention of those who wish to study the subject; and much information as to the history of revivals will be found in Gillies's *Historical Collections relating to Remarkable Periods of the Success of the Gospel*. Reference may also be made to Mrs Lundie's work on *Revivals in the British Isles*; and for the revivals in Scotland in the middle of the 18th c., to Robe's *Narrative of the Revival of Religion at Killyth, Cambuslang, and other Places in 1742* (new ed., Glasgow, 1840). Edwards maintains the genuineness of revivals with perhaps more force of argument than any writer has since done; and most of those extravagances which have sometimes attended revivals down to the present time, might have been avoided if those whose religious views accord with his had more carefully studied his discriminating remarks and sober counsels. No work has yet been produced such as Edwards in one of his letters expresses a strong desire to see—'a history of true, vital, and experimental religion, and enthusiasm, bringing down the history from age to age, judiciously and clearly making the distinction between the one and the other.'

REWAH, a state of India, called also **BAGHEL-CUND**, enclosed by the territories of the Bengal presidency, to which it is subsidiary, and having for its capital a town of the same name, which is 70 miles south-west from Allahabad, and stands on the right bank of the Tons. The town has a pop. of about 7000. It exhibits remains of former magnificence, but even the walls and the rajah's palace are much decayed. The state has an area of almost 10,000 sq. m., and great part of it is well cultivated. The pop. is about 1,200,000.

RHEYDT, a town of Rhenish Prussia, on the left bank of the Niers, and on the railway between Düsseldorf and Aix-la-Chapelle, 14 miles west-by-south from Düsseldorf. It has manufactures of silks and velvets, soap, glue, vinegar, and leather, dyeworks, and some trade in linen. Pop. (1864) 11,417.

RICORD, PHILIP, a distinguished French physician, was the son of a wealthy ship-owner, and was born on the 10th of December 1800, at Baltimore, whither his father had gone in 1790, to repair his fortunes, which he had lost under the India Company. He came in 1820 to Paris, where he was attached in succession to the Hôtel-Dieu under Dupuytren, and to the Pitié under Lisfranc. He graduated as Doctor in Medicine in 1826; but was unable, from the scantiness of his private means, to begin practice in Paris. His professional career, therefore, commenced at Olivet, near Orleans, and was thence transferred to Crouty-sur-Ouq, where he rapidly rose to distinction as a practitioner. In 1828, he returned to Paris, where he delivered two annual courses of lectures at the Pitié on surgical operations; and was appointed surgeon-in-chief to the hospital for venereal diseases. This post he held with brilliant success till his retirement in October 1860. It was here that he won his world-wide

reputation in the specialty which he had chosen—a reputation which he owed to his combination of accurate physiological and pathological knowledge, with great manual dexterity as a surgeon, and felicitous inventiveness and resource as a physician. He did much to improve the classification of enthetic diseases; and, at the Venereal Hospital delivered annually, from 1834, a course of lectures on Syphilology, for which a special amphitheatre was granted to him. For his suggestions on the cure of varicocele and on the operation of urethroplasty, he received in 1842 one of the Montyon prizes. M. R.'s practice is the most extensive and the most lucrative in Paris, inasmuch that while an inmate of the debtors' prison at Clichy, he was literally besieged by crowds of patients. He has been since 1850 Member of the Imperial Academy (section of Surgical Pathology); Member of the Surgical Society; and consulting-surgeon to the Dispensary of Public Health. By a decree of the 28th of July 1862, he was appointed Physician in Ordinary to the Household of Prince Napoleon; having already on the 12th of August 1860 been raised to the distinction of Commander of the Legion of Honour. His works are numerous, the more important of them being these: *On the Employment of the Speculum Bivale* (1833), invented by himself; *On the Bleorrhagia of the Female* (1834); *On the Employment of Mercurial Ointment in the Treatment of Erysipelas* (1836); *The Monography of Chancre* (in which he gives a detailed exposition of his own system); *Theory of the Nature and Treatment of Epididymitis* (1838); *Treatise on Venereal Maladies* (1838); *On Bleorrhagic Ophthalmia* (1842); *Iconographical Clinic of the Venereal Hospital* (1842—1851); and *On Syphilisation and the Contagion from Secondary Accidents* (1853). He has also contributed to the medical journals a multitude of Memoirs, Observations, Researches, and Communications on his specialty. His latest work is that entitled *Letters on Syphilis* (3d ed. 1857), which, from their fluency and grace of style, have earned for him the name of the Marivaux of medicine.

RIESI, a town of Sicily, in the province of Caltanissetta, and 13 miles south from Caltanissetta. It is situated at the base of a mountain of the same name, not far from the left bank of the Salso. There are sulphur-mines in the mountain. Pop. (1861) 9289.

RIOBA'MBA, a town of Ecuador, 100 miles south from Quito, situated among the Andes, on an affluent of the Pastasa, a large branch of the Amazon. It is sometimes called New R., having been built instead of a former town of the same name, which was destroyed by an earthquake in 1797, and the ruins of which are 9 miles distant, at the foot of Chimborazo. Pop. (1863) 16,000, in great part consisting of Indians.

RISTORI, ADELAIDE, a celebrated Italian tragic actress, was born in 1821 at Cividale in Frioul. Her parents were strolling players, and she almost began life in the theatre. At the age of 14, she played in *Francesca da Rimini*, and in a few years became the leading Italian actress. Her talents, her beauty, and her grace made her a universal favourite. In 1847, her marriage with the Marquis Capranica del Grillo temporarily interrupted her dramatic career; but after an interval of two years, she returned to the stage, and appeared at Rome in Alfieri's tragedy of *Myrrha*. But the French attack on the city caused her to desert the theatre for the hospital, where she employed herself assiduously in nursing the wounded. After having acted in 1850 and succeeding years at Rome

and Turin in various characters of Alfieri with immense applause, she presented herself before a French audience in 1856, when Rachel was in the height of her fame, a proceeding considered in the light of a challenge by the first Italian actress to the first French actress. Even at Paris she obtained a triumph, her genius creating an enthusiasm which could not be repressed. Without all the sympathetic sensibility of Madame Rachel, she surpassed her in vivacity and expansion. The Marchesa Capranica del Grillo was left a widow in 1861.

RITUALISM, the name popularly but inaccurately given to the remarkable increase of ceremonial in the Church of England since the year 1863. It may be considered as a development of Tractarianism, though it is one not contemplated by the authors of that movement, whose aim was rather to disseminate doctrines than to introduce ritual changes. Its collateral causes may be said to be: (1) The great advance of æsthetic taste, and the increased cultivation of the fine arts in the service of religion. (2) The extended study by the clergy of ancient liturgies, and the connection discovered to exist between them and the offices of the English Church. With the spread of High Church principles, certain changes in the mode of conducting divine service had been introduced by the clergy, which, though unpopular at first, were widely adopted, and up to a certain point, had received the sanction of the law. But the restored church with low and open benches—the separated chancel—the altar-table with coverings of different colour according to the ecclesiastical seasons, and candlesticks, and a cross upon or over it—choral services, and weekly celebration of the communion, were all that had hitherto been attempted. To these comparatively small alterations, important additions have recently been made—viz. (1) Special vestments at the celebration of the holy communion, and at certain other times, viz., for the celebrant, an alb and stoles, of different colour, and chasuble; for the assisting ministers, albs with tunicles, according to the seasons. At other times, a cope is worn instead of a chasuble. (2) Lighted candles on the altar at holy communion. (3) Incense burned either in a 'thurible' or in a standing vessel. (4) The mixing of water with wine for the communion. (5) The use of wafer-bread. (6) Elevation of the elements either during or after consecration. (7) The attendance of non-communicants at the holy communion. (8) Processions with crosses, banners, and vested attendants.

These innovations are defended by their promoters on the following grounds of (a) Law, (b) Doctrine, and (c) Expediency.

(a) The rubric at the end of the calendar in the Book of Common Prayer enacts 'that such ornaments of the church and of the ministers thereof at all times of their ministration shall be retained and be in use as were in this Church of England by the authority of parliament in the second year of the reign of King Edward VI.' The Judicial Committee of the Privy Council in the case of *Westerton v. Liddell* (1857), ruled that 'ornaments' here means, 'all articles used in divine service;' that the words 'by authority of parliament,' &c., refer to the first Prayer-book put forth in that reign (1549); and that 'the meaning of the rubric, as of the previous statute of Elizabeth, the language of which it adopts, is, that the same dresses, utensils, and articles which were used under the first Prayer-book of Edward VI. may still be used.' Now, the first Prayer-book of Edward VI. prescribes that at the time of the communion 'the priest that shall execute the holy ministry shall put on him a white alb plain with a

vestment, i. e., a chasuble, or cope;' and the assistants 'likewise the vestures appointed for their ministry, that is to say, albs with tunicles.' It is therefore inferred that the above are the only legal vestments in which the holy communion should be celebrated. To this it is objected (1) That the word 'retained' can only refer to such vestures as were in use up to the time of the last publication of the rubric—viz., the surplice in parish churches, and copes in cathedrals. (2) That the rubric, when first inserted under Elizabeth, was limited by the Injunctions and Advertisements of that reign, which aimed only at the restoration of the surplice. (3) That whatever be the intention of the rubric, it has been so long obsolete that it is absurd to revive it. It is answered (1) That the word 'retained' must have the same meaning that it had in the rubric of Elizabeth, in which it first occurs. (2) That the Injunctions and Advertisements were not of supreme authority, and were only intended to help towards restoring a decent uniformity in divine worship. (3) That the fact that a law has become obsolete does not invalidate its force. The same reference of the ornaments rubric to the second year of Edward VI. is held to authorise other accessories known to have been in use at that time, though not specified in the first Prayer-book—such as lighted candles, incense, &c. And on the principle, that the Reformed Church was legally identical with that before the Reformation—which the 30th canon of 1603 is cited as maintaining—it is further contended that all ancient laws and usages are still in force, except where directly or implicitly abrogated by subsequent enactment. And as the chief ritual authority before the Reformation was the liturgy of Sarum (the Sarum 'use' referred to in the preface to the present Prayer-book), it is to that standard, as far as possible, that the more advanced Ritualists desire to conform.

(b) The doctrinal grounds of defence are expressed in the following statements: (1) The Eucharist (as the Lord's Supper was anciently called) is the special institution of Christ, the single rite of continual observance which He enjoined on His disciples, and the chief act of Christian worship. It is therefore right to exalt and dignify it above all other services, and mark it as standing on different and higher ground than any other institution. (2) The Eucharist, according to the universal belief of the ancient church, is to be regarded as a sacrifice, commemorative, as the Jewish sacrifices were anticipatory, of the death of Christ—not as iterating or repeating it (which idea alone the 31st article is held to condemn), but as a solemn pleading and offering of it before God, as Christ himself offers it in heaven. Hence the position of the celebrant in front of the altar, and the use of a sacrificial vestment, as the chasuble is held to be. (3) In the Eucharist, there is a real presence of Christ, which, though spiritual, is objective, i. e., not dependent on the receiver, but as a result of consecration, and to a certain extent local. (The growth of this belief is marked by the change made in a recent edition of Keble's *Christian Year* of the words, 'not in the hands,' in a poem on the Eucharist, to, 'as in the hands.') Hence distinct acts of adoration, addressed, not, as is explained, to the elements, but to the Divine Presence, of which they are the vehicles and signs.

(c) On the ground of expediency also, it is contended: (1) That experience proves that the only way of attracting and gaining a hold on the vast uneducated masses of our towns and cities is by a worship addressed not merely to the ear, but to the eye. 'Ritualism,' says one of its defenders, 'is the object-lesson of religion.' Services conducted in grand and

beautiful buildings—brilliantly lighted—with splendid vestments, touching music, costly decorations, and every outward token of reverence and solemnity, will impress the young and the poor as nothing else can do. Those churches in London where advanced ritual prevails are said to be thronged with worshippers—mainly of the lower classes, and in great proportion of men—when others are almost empty. (2) A further argument, under this head, is connected with the desire, which has grown up of late years among the High Church party, for the restoration of the visible unity of Christendom, and specially the renewal of communion between the Church of England and both the Eastern and the rest of the Western Church; and with this view, it has become an avowed object to assimilate the Anglican service as much as possible to that of other Catholic churches.

It remains to notice briefly the effect of these innovations. It is a remarkable index of the change of popular feeling within the last ten years, that such bold and startling changes, altering the whole character of the Anglican service, should, by a large number of people be not only tolerated, but approved. In 1859, the attempt of the rector of St George's-in-the-East to introduce Eucharistic vestments, led to riots which convulsed the whole of East London. In the year 1867, in about twelve churches of the metropolis—and in several country towns and villages—a far more advanced ritual, with vestments, altar-lights, and other ceremonies, appears to attract an eager throng, not of spectators only, but of worshippers. And the spread of the movement may be judged by the statement, which appears authorised by facts, that since the publication of the first Report of the Royal Commissioners on Ritual, the vestments have been introduced in more than thirty churches. On the other hand, among the 'Protestant' members of the church, and those of other denominations, the movement has provoked the loudest opposition. Most of the bishops have, directly or indirectly, expressed their disapprobation; the press, except two or three journals, which are its strenuous advocates, is almost unanimous in denouncing it; the more moderate members of the High Church party discourage it; and active efforts have been made to arrest it by legislative interference. In the Lower House of Convocation, on the motion of the Dean of Ely, a committee was appointed to consider the subject, which, after careful examination, reported, in June 1866, that vestments and altar-lights, whether legal or not, should not be introduced without sanction of the bishop; that the censuring of persons and things, elevation after consecration, wafer-bread, and presence of non-communicants (except in special cases), were to be discouraged. In deference to this opinion, the censuring of persons and things has been in some churches given up. Suits have been instituted in two cases—one against the Rev. A. H. Mackonochie, incumbent of St Albans, London; and the other against the Rev. T. B. Simpson, in the diocese of Exeter. The points complained of in these are chiefly elevation and the mixed chalice. In the beginning of the year 1866, an opinion was obtained, at the instance of some of the bishops, from five eminent counsel, among whom were Sir R. Palmer and Sir Hugh (now Lord) Cairns, against the legality of all ritualistic innovations (the main grounds of which opinion are given in the *objections* above stated). In reply to this another opinion was obtained, by the Council of the English Church Union, from nine leading counsel—three of whom have since been raised to the bench—all of whom advise in favour of the

legality of vestments, all but two in favour of altar-lights, and all against incense; on the mixed chalice and wafer-bread, they are nearly equally divided.

In the session of 1867, the Earl of Shaftesbury introduced a bill—founded on the 58th canon of 1603—to limit ecclesiastical vestments to the ordinary surplice and hood, in favour of which more than 600 petitions were presented; while one against it, presented by Lord Redesdale, was signed by more than 9000 clergy and lay communicants. (An earlier memorial, to the Archbishop of Canterbury, against any change in the existing law, was signed by more than 40,000 communicant members of the church.) This bill was withdrawn on the appointment by the government of a Commission 'to inquire into the Rubrics, Orders, and Directions for regulating the course and conduct of Public Worship, &c., according to the use of the United Church of England and Ireland.' The commissioners were: the Archbishops of Canterbury (Longley) and Armagh (Beresford); the Bishops of London (Tait), St Davids (Thirlwall), Oxford (Wilberforce), and Gloucester and Bristol (Ellicott); Earls Stanhope, Harrowby, and Beauchamp; Lords Portman and Ebury; Sirs Joseph Napier, W. Page Wood, Robert Phillimore; Deans Stanley of Westminster, Goodwin of Ely, and Jeramis of Lincoln; Drs Travers Twiss, D.C.L., and Payne Smith, Reg. Professor of Divinity at Oxford; Messrs Walpole, Cardwell, J. D. Coleridge, Beresford Hope, Abel Smith, J. G. Hubbard; Revs. H. Venn, J. G. Humphry, R. Gregory, Thomas W. Perry. They met 19 times, examined 17 witnesses—chiefly leading clergy of different parties—and on August 19 published their first Report, to the effect, that 'it is expedient to restrain, in the public services of the church, all variations in respect of vesture from that which has long been the established usage of the said church; and that this may be best secured by providing aggrieved parishioners with an easy and effectual process for complaint and redress.' They do not, however, recommend any way of carrying this into effect. Three of the commissioners sign with reservation; two (Sir R. Phillimore and Mr Beresford Hope) excepting cases where the authority of the bishop, and the rights of parishioners and congregations, are carefully guarded; and one (Rev. T. W. Perry) limiting the meaning to those cases where grave offence is likely to arise, and the term 'aggrieved parishioners' to communicants having reasonable ground of complaint. The evidence appended to the Report supplies valuable information as to the various practices prevailing, and the widely different views entertained. The general result would appear to be that vestments, and probably altar-lights, and the mixed chalice are legal; that an ornate ritual is useful among some classes, and might, with certain safeguards, be allowed; that absolute uniformity is impossible, but that the law might be obeyed a good deal more generally than it is; that the maintenance of the present law, with a wide and liberal interpretation, allowing for differences of education and temperament, but limited as a maximum to the ritual of the 2d year of Edward VI., with an honest compliance on the part of the clergy, and some recognised ecclesiastical authority to restrain unauthorised variations, whether of excess or defect—would be most for the welfare of the church.

RI'ZAH, a town of Asiatic Turkey, in the pashalic of Trebizond, on the coast of the Black Sea, 40 miles east from Trebizond. It is a place of considerable trade, and has manufactures of fine hempen fabrics. Pop. 30,000.

ROBERTS, DAVID, R.A., a painter of great

eminence, was born at Edinburgh on 24th October 1796, and began life there as apprentice to a house-painter. His talent for art becoming obvious, he was set to study at the Trustees' Academy; and in 1822 he went to London, where he found employment as a scene-painter at Drury Lane Theatre. Clarkson Stanfield, since famous as a marine-painter, was then also working at Drury Lane, and between him and R. an affectionate intimacy ensued, which ceased only with life. In 1826, a picture of 'Rouen Cathedral,' exhibited by R. at the Royal Academy, drew attention by its marked ability. The year after, appeared his painting of 'St Germain's at Amiens.' Shortly after, he left England, and for seven years was engaged in sketching in Spain, Africa, and the East. As result of his labours, there was given to the world in 1839 the splendid work, in 4 vols., entitled *Sketches in the Holy Land, Syria, Idumæa, Arabia, Egypt, and Nubia*. The book contains 246 subjects, lithographed by Louis Haghe, and illustrated by a historical commentary furnished by Dr Croly. It is the finest and most elaborate thing of the kind perhaps ever produced, and of itself it would have sufficed for a great reputation to the artist. Pending its appearance, he had resumed his contributions to the Academy, of which in 1839 he was elected an Associate; the full dignity of Academician being conferred on him two years after. From this time forward, he grew steadily in fame, and in 1854 he was selected by the Queen to paint for her the 'Inauguration of the Great Exhibition in 1851;' a task which he achieved with admirable success. In his chosen field of architecture, during all his later life, he was admittedly without a rival. In addition to his unremitting work for the Academy, he illustrated many books, and issued the admirable series of lithographs, 'Spanish Sketches,' which attained a great popularity. He died November 25, 1864.

ROBERTSON, JOSEPH, the most accomplished Scottish antiquary of the present century, was born at Aberdeen on the 17th day of May 1810. He was educated at Udry, in his native county, at the grammar-school of Aberdeen, and afterwards at the Marischal College there. The law was chosen for him as his profession, but his heart was not in the task, and from an early age he devoted himself to literature. His chief attention then, as in his after life, was directed to researches connected with the history and antiquities of Scotland; and in 1833 he went to Edinburgh, the place of all others best adapted for the cultivation of his favourite studies. While there, he wrote, for Oliver and Boyd's Cabinet Cyclopaedia, a volume on the *Circumnavigation of the Globe*, which was published in 1836. The work by which he became first generally known, *The Book of Bon-accord, or a Guide to the City of Aberdeen*, was published in 1839. It is justly styled by Mr Charles Knight, in his *Life of Shakspeare*, 'a most lively, instructive, and learned volume—a model of guide-books.' A continuation of this work was promised, but was never completed. In the following year, his *Deliciae Literariae, a new volume of Table-talk*, was published. In 1839, he returned to the north to undertake the editorship of the *Aberdeen Constitutional* newspaper; and in the end of that year, in conjunction with Mr John Stuart, he founded the Spalding Club, a society instituted for printing the historical, ecclesiastical, genealogical, topographical, and literary remains of the north-eastern counties of Scotland. This society, formed on the model of the Bannatyne and Maitland Clubs, has printed many valuable works on Scottish archaeology, which otherwise would have been all but inaccessible. Its earliest publication was a *History of Scots Affairs from 1637 to 1641*,

written by James Gordon, parson of Rothiemay, which was issued in three vols. in 1841, under the joint editorship of Mr R. and Mr Grub. R. edited for the same Club a volume of *Collections for a History of the Shires of Aberdeen and Banff* (1843); three vols. of *Illustrations of the Topography and Antiquities of the Shires of Aberdeen and Banff* (1847, 1857, and 1862); and *Passages from the Diary of General Patrick Gordon of Auchleuchries* (1859). He also contributed to the fifth volume of the Miscellany of the Club, in 1852, a learned paper *On Scholastic Offices in the Scottish Church in the 12th and 13th Centuries*. In 1843, R. went to Glasgow to become editor of the *Glasgow Constitutional* newspaper. While in that city, he edited for the Maitland Club, in 1846, a volume containing the *Book of the Collegiate Church of St Mary and St Anne, Glasgow*, and the *Chartulary of the Black Friars of Glasgow*; and in 1847, the fourth volume of the Miscellany of the Club. In June 1849, he contributed to the *Quarterly Review* an article on Scottish Abbeys and Cathedrals, which has become a text-book for all who write on that subject. In the same year he once more took up his residence in the Scottish metropolis, on being appointed editor of the *Edinburgh Evening Courant*. He discharged his editorial duties at Aberdeen, Glasgow, and Edinburgh with faithfulness and ability; but he found a more congenial occupation, when, in 1853, he was appointed, through the Earl of Aberdeen, who knew and appreciated his merits, to the office which is now known as that of Curator of the Historical Department of the Register-house at Edinburgh. In 1863, he edited for the Bannatyne Club the *Catalogues of the Jewels, Dresses, Furniture, Books, and Paintings of Mary Queen of Scots*. This volume contains a Preface which forms a most valuable contribution to the history of Mary's reign, and supplies information on almost all the controversies connected with her life. With the sanction and zealous encouragement of Sir William Gibson-Craig, Lord Clerk-register of Scotland, he projected the publication of a series of works connected with the history of Scotland, similar to those which have appeared in England under the direction of the Master of the Rolls. The first volume of that series, containing the *Chronicles of the Picts and Scots*, has recently been published under the editorship of Mr Skene. R. assisted in other literary undertakings, and was a valuable contributor to this *Encyclopaedia*. His articles are generally connected with his favourite studies; among them are those on ARCHÆOLOGY, BURGH, ST COLUMBA, CRANNOGERS, the CULDEES, DAVID I., the FAMILY OF DOUGLAS, IONA, MARY STEWART, and OSSIAN. The last and most important of R.'s works was his *Concilia Scotiae*, printed in two vols., in 1866, for the Bannatyne Club. This work has done for the Scottish Church that which Archdeacon Wilkins did for the Church of England in his *Concilia Magnae Britanniae et Hiberniae*. It contains the statutes of all the Scottish councils, whether provincial or diocesan, from the earliest period to the Reformation, printed carefully from the best authorities; and the Preface, which occupies the greater part of the first volume, is a learned and authentic history of the councils, and of everything bearing on the subject of them. The authorities are quoted with an accuracy and copiousness for which R. was remarkable, and which contrasts strongly with the carelessness in that respect which marks some popular historians of the present day. In April 1864, R. received the degree of LL.D. from the University of Edinburgh. He died on December 13, 1866, almost immediately after the publication of his *Concilia Scotiae*. R.'s labours are

not to be estimated merely by the works which appeared under his name, or which he is known to have written. There is hardly a work of any merit published during the last twenty years, in connection with Scottish history and antiquities, to which he did not in some way or other give his assistance; and his assistance was given with a thorough heartiness which only those who have benefited by it can appreciate. No literary man of his time was more beloved by his friends and intimate associates. In the relations of private life, he was most exemplary.

RO'BIN, besides being a familiar name of the Redbreast (q. v.) in Britain, and frequently given to the Bluebird (q. v.) in America, is also in America the usual name of a species of Thrush (q. v.) widely distributed from Mexico to lat. 60° N. It is nearly twice the size of the redbreast, olive gray, the top and sides of the head black, the chin and throat white with black streaks, the under parts chestnut brown. It remains during winter in sheltered places, even as far north as New England, but is generally a bird of passage. Many arrive in New England before the snow has disappeared. Large flocks are to be seen in the Southern States in winter, where great numbers are killed for the table, the markets being often glutted with them. In Massachusetts, the law forbids the killing of this bird at any season of the year. Its nest is often built near houses. Two broods are produced in the year. The robin is a lively bird, and a general favourite in the northern parts of the United States. It is often kept as a cage-bird, is very gentle and easily tamed, and has a pleasing song.

ROHTU'K, a town of British India, the capital of a district of the same name, in the great territorial division of Delhi, North-west Provinces, 42 miles north-west from Delhi. A canal or water-course, 45 miles long, constructed by order of the British government in 1825, supplies R. and the neighbouring country with water from the great Feroze-shah Canal. Pop. about 13,000.

RONDELET, WILLIAM, a French naturalist, born at Montpellier in 1507; died 1566. He became a medical practitioner in Montpellier, and professor in the medical school there. He was a zealous student of natural history, and particularly distinguished himself in ichthyology. His *Histoire entière des Poissons* (Lyon, 1558) was one of the first works which contributed much to the progress of that branch of science.

ROSA RIO, a town of the Argentine Republic, on the right bank of the Parana, 170 miles north-west from Buenos Ayres, 210 miles by river. It is the most important town on the Parana, and is rapidly increasing in population and commerce. The customs duties in 1854 amounted to £68,074, and in 1862 to £131,103. There is reason to think that the increase proceeds at a still more rapid rate. The exports are much the same as those of Buenos Ayres. Pop. (1860) 30,000.

ROSSIENY, a town of European Russia, in the government of Kovno, 66 miles north-west from Kovno, on the Dubitzka, a branch of the Niemen. Under the Polish government, it was the capital of Samogitia. Pop. (1863) 12,465.

ROTA, a town of Spain, in the province of Cadiz, and six miles north-north-west from Cadiz, on the opposite side of the entrance of Cadiz Bay. Rota wine has acquired some celebrity, and is brought to the British market. Pop. 8000.

ROTA'TION OF CROPS. The plants like the animals of the farm differ much in their habits, and

in the different sorts of food on which they subsist. The broad-leaved clovers, turnips, and mangold abstract from the air a large proportion of the materials of their growth; whilst the narrower-leaved grains and grasses, especially if their seeds are ripened, partake more largely of mineral food withdrawn from the soil. The cereals require for their healthy nutrition large supplies of phosphoric acid and silica; leguminous plants devour a large share of lime; turnips, carrots, and clover take up a great amount of potash. Corn-crops, occupying the ground during the greater part of the year, favour the growth of weeds; well-tended root-crops, on the other hand, afford better opportunity for deep culture, for the extirpation of weeds, for the convenient application of manures; whilst, being in great part consumed on the land, they raise its fertility. Mainly from such considerations, the farmer of arable land is led to grow a succession of dissimilar plants, or, in other words, to adopt a rotation of crops. The cereals exhausting the farm, on account of their ripened seeds being sold off, are generally alternated with fallow, root, or cleansing crops, or with beans and peas, which occupy a kind of intermediate position between the cereals and the roots; whilst clovers or grasses are taken at intervals of six or eight years. The rotation most suitable for a particular farm is, however, greatly modified by various circumstances, and especially by the nature of the soil, climate, markets, available supplies of extra manures, amount of live-stock kept, &c. That course of cropping is evidently the most desirable which will economically secure, with thorough cleanness of the soil, a high and increasing state of fertility.

Many rotations are based upon the Norfolk or four-course system, which consists of (1) Clover or mixed grass seeds; (2) Wheat, or in many parts of Scotland, oats; (3) Turnips, Swedes, mangold, potatoes, or bare fallow; (4) Barley. The details of this system are generally as follows. The clovers or grasses are mown or grazed; when cut, they are either used green or are dried for hay; the second crop is carted home for the cattle or horses; near towns, it is sold off; or it is consumed on the ground in racks by sheep, which on most highly cultivated farms receive besides a daily allowance of cake or corn. In districts where town-manure can be obtained, a top dressing is applied as soon as the first crop of grass is cut. On the poor and worse cultivated soils, the grass-crop occasionally remains down for two, or even three years, thus extending a four into a five or six years' rotation. The clovers or mixed seeds are ploughed up in autumn, and followed generally in England by wheat, and in Scotland by oats. These crops are now usually drilled, to admit of horse and hand hoeing. After harvest, the stubble is, if possible, cleaned by the scarifier, grubber, or plough and harrows; or, where the management for several years has been good, any patches of couch-grass or other weeds are best forked out by hand. The land, especially if heavy, or intended for mangold drilled on the flat, as practised in the drier parts of England, may then be manured and deeply ploughed: the grubber and harrows, in April or May, suffice to prepare for the drilling of mangold or Swedes. Heavy land, intended either for roots or barley, should, in spring, be ploughed or disturbed as little as possible. In Scotland, and the cooler moist climates of the north and west of England, turnips and potatoes are grown on raised drills or balks, in which the manure lies immediately underneath the plant. Frequent horse and hand hoeings should insure the thorough cleaning of the crop. Unless in the neighbourhood of towns, where it is greatly more

ROTATION OF CROPS—ROTTLERA.

profitable to sell off the whole of the root-crop, part of the Swedes or mangold is taken home for the cattle, but the largest portion is consumed by sheep in the field. After the fallow or cleaning crop, another cereal crop is grown: under the Norfolk system, this is generally barley, with which the clovers or seeds are sown out. Where sewage or tank water is available, Italian rye-grass is often used, and on land in high condition, early large and repeated cuttings are obtained; but rye-grass has the disadvantage of being a worse preparation than clover for the wheat-crop which usually follows. The chief failing of the four-course system consists in the frequent recurrence of clover, which cannot be successfully grown oftener than once in six or eight years. To obviate this difficulty, one-half of the clover quarter is now often put under beans, peas, or vetches, thus keeping the grass or clover seeds eight years apart.

The Norfolk four-course system is unsuitable for heavy land, where a large breadth of roots cannot be profitably grown, and where their place, as a cleaning crop, is taken by bare fallow, vetches, or pulse. Bare fallows are, however, less frequent than formerly, being now confined to the most refractory of clays, or to subjects that are so hopelessly full of weeds as to require for their extirpation several weeks of summer weather, and the repeated use of the steam or horse ploughs, the scarifier, grubber, and harrows. In such circumstances, winter vetches are often put in during September or October, are eaten off by sheep and horses in June or July, and the land afterwards cleaned: this practice is extensively pursued on the heavier lands in the midland and southern counties of England. In such localities, the following system is approved—(1) The clover leas are seeded with (2) wheat; then come (3) beans, pulse, or vetches, manured, horse or hand hoed; (4) On good land, wheat succeeds; (5) Oats or barley often follow, but, to prevent undue exhaustion of plant-food, this system requires considerable outlay in artificial manures, cake, and corn; (6) A fallow, or fallow crop, deeply and thoroughly cultivated, and well manured, comes to restore cleanness and fertility; (7) Barley or wheat is drilled, and amongst this, the clover-seeds are sown. On the heavier carse-lands in Scotland, the following plan of cropping is generally practised—(1) Clover; (2) Oats; (3) Beans; (4) Wheat; (5) Bare fallow or fallow crop, usually including a considerable breadth of potatoes; (6) Wheat; (7) Barley, with which the clovers or mixed grasses are sown. Under this system, it is difficult, with so few cleaning crops, to keep the land clean; roots, besides, are not produced in quantities sufficient properly to supply either cattle or sheep during the winter. To remedy these defects, roots may be introduced after the oats, and would be followed either by wheat or barley. This extends the rotation from seven to nine years.

In all well-cultivated districts, whether of heavy or light land, stock-farming is extending, and a more vigorous effort is being made to raise the fertility of the land. Root-crops are accordingly more largely grown; indeed, it is sometimes found profitable to grow two root-crops consecutively; thus, after turnips, Swedes, cabbage, or mangold, well manured from the town or farmyard, and eaten off by sheep, potatoes of superior quality are produced with one ploughing, and a dose of portable manure. Specialities of management occur in almost every locality. In Essex, winter-beans follow wheat, are got off in August, and are succeeded by common turnips. Near London, and in other southern districts, early potatoes or peas are grown for market, and are immediately followed by turnips. In many parts of England, where the soil and

climate are good, rye or vetches sown in autumn are consumed in early summer, and a root-crop then put in.

Good rotations do not necessarily insure good farming; they are merely means to an end. By carefully removing weeds, by deeply stirring the soil, and by applying appropriate manures, wheat may be grown on the same soil for an indefinite number of years. At Lois-Weedon, in Northamptonshire, the Rev. S. Smith has for twenty years cultivated alternate three-foot strips of wheat and well-forked bare fallow; the land that is wheat this year being fallowed next. Although no manure whatever is applied, and only one-half of the experimental plot is each year under crop, the yield continues to stand at four quarters per acre, which is about four bushels per acre in excess of the average acreable produce of Great Britain. The Lois-Weedon system, owing to the outlay which it entails for manual labour, probably could not be carried out with profit on a large scale. It demonstrates, however, the inherent resources lying dormant, especially in clay-soils, and indicates how they may be rendered available by thorough cultivation. It is mainly by such cultivation that steam-power proves so serviceable in our fields. The soil is turned up deeply to the disintegrating solvent influences of wind and weather; the necessary operations are rapidly overtaken in good season; much work is accomplished in autumn; treading and poaching of the surface is avoided; whilst a larger breadth of roots is attainable for the healthy and economical support of the sheep and cattle stock, which not only directly enhance the returns of the farm, but also raise rapidly its manual condition.

As agricultural education and enterprise extend, fixed rotations will be less regarded. The market-gardener, who extracts a great deal more from his land than the farmer has hitherto been able to do, does not adhere to any definite system of cropping. If the farm is kept clean and in improving condition, there can be no harm in growing whatever crops it is adapted to produce. Cropping clauses are only requisite during the three or four last years of a tenancy. The restrictions found in some agreements, preventing the growth of clover for seed, flax, and even potatoes, are inadmissible. Equally objectionable are clauses against the sale of particular sorts of produce, such as hay or roots. The farmer, if he is fit to be intrusted with the use of the land, ought to be permitted to grow or sell off any crop he pleases, provided an equivalent in manure be brought back. On well-cultivated land, in good condition, it is now the practice of the best farmers to take oats or barley after wheat; indeed, some of the best malting barley in Essex, on the Scottish carse-lands, and elsewhere, is now grown after wheat. The frequent growth of cereals, and the heaviest of hay and root crops, even when removed from the farm, may be fairly compensated for by large doses of town-dung or of sewage. The plant-food disposed of in the more ordinary sales of the farm is economically restored by the use of bones or superphosphate, guano or nitrate of soda, or by keeping plenty of sheep, penning them over the land, and supplying them liberally with cake and corn.

ROTTLERA, a genus of trees of the natural order *Euphorbiaceæ*, with a 3–5 parted calyx, no corolla, 30–40 stamens springing from the convex receptacle, and a 2–4 coccous capsule, each portion having one seed. The species are rather small trees, found in India and other tropical parts of Asia. *R. tetracocca* grows in Sylhet, and yields a hard and valuable timber. *R. tiactoria* is a native of India,

from the Coromandel coasts to the northern forests. Its capsules are covered with short stiff hairs, which, when rubbed off, have the appearance of a fine red powder, are used in India for dyeing silks scarlet and orange, and form an article of commerce in that country. Professor Anderson of Glasgow has examined this dye-stuff, and in the *Edinburgh Philosophical Journal* for April 1855, has stated his opinion that it merits the attention of silk-dyers. The colour which it yields is of great beauty and great stability.

ROUHER, Eugène, a very eminent French statesman, was born at Riom, on November 30, 1814. He first distinguished himself as an advocate at the bar of his native town, at which he practised up to 1848. The attention of the country was first drawn to him by the ability he shewed in a press prosecution, in which he was engaged for the defence. In 1848, he was returned by the department of Puy-de-Dôme to the Constituent Assembly, which was summoned after the revolution of that year, and in the following year he was returned to the Corps Législatif by the same department. On the break-up of Odillon Barrot's cabinet, the first ministry of Louis Napoleon, towards the end of 1849, R. was appointed Minister of Justice; and with slight interruptions, he has been since then a member of the French government. In the Corps Législatif, he shewed himself a moderate politician; and he never affected to consider the Republic an improvement on the constitutional system which had preceded it. In 1852, he was appointed Vice-president of the Council of State, with the oversight of the departments of Legislation, Justice, and Foreign Affairs. In 1855, he was appointed Minister of Agriculture, Commerce, and Public Works, and in this office he found extraordinary opportunities for the exercise of his administrative ability. In the negotiation of the Treaty of Commerce with England, which—much decried both in France and in England at first—is now admitted to have conferred immense advantages upon both countries, the negotiations were conducted by M. R. and M. Baroche on the part of France, by Lord Cowley and Mr Cobden on the part of England; the treaty was signed on January 22, 1860. The arrangements consequent upon the treaty involved immense labour and manipulation of details, and the chief part in adjusting them devolved upon M. R. and Mr Cobden. In 1863, he negotiated a Treaty of Commerce between France and Italy, receiving from the king of Italy, in acknowledgment of his merits, the Orders of St Maurice and St Lazaire. He has thus been the chief instrument in the introduction, or in preparing the way for the introduction, of free trade as the commercial policy of France and the neighbouring continental countries.

In June 1863, M. R. retired from the ministry of Agriculture and Commerce, and was appointed President of the Council of State in succession to M. Baroche. Soon after, he took the office of Minister of the Interior; and in October 1863, on the death of M. Billault, he was appointed Minister of State. In this office, he had to represent the government as 'talking-minister' in the Corps Législatif; and it is admitted that he has had no superior as a debater among the great orators, trained under the constitutional system, who are still members of that body. His reputation as a debater stands as high as his reputation as an administrator; and it may safely be said that he has no superior, if any equal, for ability among the French politicians of the time. In January 1867, when the emperor, by a decree, introduced certain modifications of the privileges of the Corps Législatif, and of the relations between that body and the ministers,

M. R., with the other members of the cabinet, resigned his office, but he was immediately reinstated in it. He was appointed a member of the French Senate on the 18th of June 1856. He became Grand Officer of the Legion of Honour in 1866; and was promoted to the rank of Grand Cross in January 1860.

ROUND-FISH (*Coregonus quadrilateralis*; see **CORREGONUS**), a fish found in the western parts of North America, from Vancouver's Island northwards, in the rivers on the western side of the Rocky Mountains, and in the Mackenzie and Coppermine rivers. It ascends the rivers in summer to spawn, spending part of its life, like the salmon, in the sea. It is a beautiful fish; seldom more than two pounds in weight, of a yellowish-brown colour, paler on the sides and belly than on the back, with bright and glittering scales, each of which is edged with a narrow band of dark gray; the mouth very small, no teeth perceptible. Before spawning, it is loaded with fat, which, on the shoulders, almost amounts to a hump; but after spawning, it becomes thin, and its flesh watery and insipid. In a good state, it is a very delicious fish, rivalling in excellence its congener, the Whitefish (q. v.). This fish is an important article of food to the Indians of North-western America, and vast numbers are caught in the rivers as they ascend from the sea. They ascend in such numbers that no ordinary contrivances of fishing are necessary, but the fish are baled out by baskets, little nets, wooden bowls, or even by the hand. They are cured by splitting and drying, like salmon. The R. readily takes a rough gaudy fly.

ROVU'MA, a river of South-east Africa, which enters the Indian Ocean by a spacious bay north of Cape Delgado. Only a small portion near its mouth was known to Europeans till 1861, when Drs Livingstone and Kirk attempted its ascent in the small steamer *Pioneer*, drawing five feet water. The river was then in flood, and had a strong current. After an ascent of 30 miles, the difficulties of the passage induced the explorers to return. Another ascent was made by the same party during the dry season of 1862. With two ships' boats, they reached the rapids which limit the navigation, above 100 miles from the coast, and half-way to the Nyassa Lake.

Passing through gloomy, unhealthy forests of mangroves, they entered a healthy plain, covered with heavy timber and brilliantly flaming tropical plants; but the country was infested by the 'tsetse fly,' a serious obstacle to its development. The river abounded with hippopotami. The travellers came within two days of the town of N'gomano, where all the caravans cross the R., but could not leave the boats in order to reach it. Here the R. is joined by the Niende, a large affluent from the hills on the south-west; while the main stream comes from the west and north-west. As the R. is navigable for only a few months of the year, it offers little advantage for commerce; but it affords an excellent entrance by which to explore the regions between the Nyassa and Tanganyika lakes. During his last African journey, Dr Livingstone and his party left Zanzibar in March 1866. Owing to the swampy state of the country, the party landed 25 miles north of the R., and striking south-south-west across the country to that river, followed it to the point where it is joined by the Leonde from the mountains on the south-west, near the eastern shore of Lake Nyassa. On their arrival at N'gomano, the travellers found the country destitute of provisions, a tribe of Mazité having swept away all the food found above ground. Dr Livingstone

proposed to establish the base of his operations at N'gomano, till he could find his way round the Nyassa; and the last authentic news of him was from a letter dated thence on the 18th May 1866. Reports of his death reached England early in 1867; but subsequent reports give good ground to hope that he is still alive, and on his way home.

ROYER-COLLARD, PIERRE-PAUL, a French statesman, born 21st June 1763, at Sompuis (Marne). The childhood of R. was spent at his father's house, under the severe surveillance of his mother, who belonged to a family ardently devoted to Jansenism. He was sent to college at Chaumont, and afterwards at Saint-Omer, which was superintended by one of his uncles, the Abbé Collard. Having passed as an advocate at an early age, he pleaded several times before the old parliament; but from the first days of the Revolution he was involved in the events of that time, having been elected one of the representatives of the commune of Paris. From 1790 to 1792, he acted as joint-secretary of the municipality. It was then that he was connected with Pétion and Danton. The events of the 31st May obliged him to remove from Paris. He then returned to Sompuis, and lived in obscurity during the whole time of the Reign of Terror, studying and following the plough himself, to evade the suspicions of the Jacobins. Three years afterwards, in 1797, the electors of this department chose him to represent them in the Council of the Five Hundred. R. took an active part in the work of that assembly. He was one of those honest men who, preferring monarchy, but fearing a violent counter-revolution, consented to try the republic with a moderate government, cherishing the hope, in the meantime, of an ultimate restoration. The 18th Fructidor completely opened his eyes and dispelled his illusions. It was then that he turned his thoughts to what he believed to be the only hope of France, and that he began a correspondence with Louis XVIII, which, however, ceased towards the epoch of the establishment of the Empire. For some years afterwards, he ceased to have anything to do with politics, and entered on another career. He was offered the chair of Philosophy (1809) by Napoleon, in the recently created University of France, which he accepted after great hesitation. Applying himself vigorously to study for it, he was soon highly qualified to fulfil his duties. In the few years he occupied this chair, he exercised an immense influence on the philosophy of France. Rejecting the purely sensuous system of Condillac, he proceeded eclectically, giving special prominence to the principles of the Scottish school of Reid and Stewart. He originated the 'Doctrinaire' school, of which Jouffroy and Cousin were the chief representatives.

The Restoration deprived the cause of education of the services of Royer-Collard. The Bourbons did not overlook the man who had not ceased, since 1798, to maintain their cause; but R., who had all along dreamed of the union of hereditary monarchy with an enlightened liberty, was ill fitted to act with the royalist fanatics now dominant in France.

R. was appointed President of the Commission of Public Instruction (15th August 1815), which office he held, with the title of Councillor of State, till July 1820. He gave in his resignation at that time, not wishing to associate himself with the politics of the ministry. In 1815, the electors of Marne chose him to represent them in the famous 'Chambre Introuvable' (q. v. in SUPPLEMENT). He took part in all the business of the Chamber, remaining steadfastly attached to the king, but energetically opposing the *ultra* party. In the next parliament, he rejected, with great energy, the idea of confiding public instruction to the clergy. 'The university,

he exclaimed, 'has the monopoly of education, nearly as much as the courts have that of justice, and the army that of the public force.'

At the end of the session 1817, R. for the first time, withdrew from the government, at least from the course pursued by the ministry. He once more supported it in a new discussion against the predominance of the Catholic Church; but dating from 1819, the rupture was complete. He presented then the singular spectacle of a devoted royalist seconding the efforts of the Liberals. The French Academy opened its doors to him in 1827; and in 1828, he was named President of the Chamber of Representatives. As President, R. had to present the famous address of the 221 deputies (March 1830), refusing their support to the government, which the king refused to hear read. Next day, the Chamber was prorogued. R. departed for Châteauneuve, his country-seat, where he went to conceal fears and regrets which the revolution of July was to justify. He was re-elected in June 1830, and he accepted this mandate. In 1842, he withdrew from parliamentary life, and after that lived in great retirement.

Although R. had a considerable fortune, he never departed from the greatest simplicity, excepting for three things—the purchase of books, charity, and the receptions which his official position imposed on him. He received with politeness, but with a certain coldness which he could never lay aside. His salon was very much frequented by the political world. Every Sunday, the principal leaders of the moderate opposition assembled there: it was a large room, serving as a study, the walls of which were hidden from top to bottom by shelves loaded with books; not a single ornament—no fine furniture—what was strictly necessary, and no more. There assembled Cousin, the most eminent of his pupils; Guizot, the Duke de Broglie, Casimir Périer, De Barante, Villemain, Ampère, Andral, De Rémusat, De Barthélemy, Gabriel, and many others. There was little conversation, properly so called; the slow and sonorous voice of R. was dominant in the room. The subjects were almost always the political events and the debates in parliament; the acts of the government were not spared. This salon was the echo of the Liberal world.

From 1842, R. had completely withdrawn from public life, his health, in fact, not allowing him to occupy himself with public matters. He spent only the winter in Paris, returning in summer to his estate of Châteauneuve, where he died, 4th September 1845.

R. was undoubtedly one of the most noted men of the 19th century. He exercised on his contemporaries a powerful influence, owing more, perhaps, to the uprightness, firmness, and extreme earnestness of his character, than to intellectual power or genius. Excepting his political speeches, published in the *Moniteur*, R. left few published works. A lecture on External Perception appeared in 1813; and his smaller contributions to philosophy are to be found in Jouffroy's translation of Reid's works (Par. 1836).

RSHEW, or RJEV, a town of European Russia, in the government of Tver, and 80 miles south-west from Tver, on the Volga, which passes through it. It is a place of much commerce, has salt and corn magazines, and two great annual fairs. Pop. (1863) 18,746.

RUELLIA, a genus of plants of the natural order *Acanthaceæ*, natives of tropical and sub-tropical parts of Asia and Australia. Some of them are very beautiful, and are common ornaments of our hothouses. In some parts of China, especially in the province of Che-kiang, and on the mountains

to the west of Ning-po, a species of this genus, *R. indigofera*, is much cultivated for the excellent indigo which it yields. It is also a native of Assam, and is cultivated there.—See Fortune's *Residence among the Chinese*.

RUMA'NIA (often written **ROUMANIA**). See the article **MOLDAVIA AND WALACHIA**. Since that article was published, important political changes have occurred in Rumania. A military revolt took place in February 1866, which resulted in the deposition of Prince Couza—Alexander John I. His palace at Bucharest was invaded by the soldiery; he was made prisoner, and forced to sign his abdication. In both houses of legislature, the Count of Flanders, younger brother of Leopold II. of Belgium, then in his 19th year, was unanimously chosen Hospodar, and he was proclaimed by the style of Philip I.; but he at once declined the perilous honour. Upon this, the choice of the Rumanians fell upon Prince Charles of Hohenzollern-Sigmaringen, who was proclaimed Prince of R. on April 20, 1866, and continues (1868) to occupy the Rumanian throne.

R'USSIAS, ALL THE, the official designation of the Russian Empire in Europe, was assumed in 1654, when the Czar Alexei Mikailowitch styled himself for the first time 'Tzar of All the Russias,' after his conquest of Little Russia and acquisition of Smolensk from Poland. This phrase at first included Great Russia, White Russia, and Little Russia, though in later times it acquired a more comprehensive signification. *Great Russia*, formerly called Muscovy, which is by far the largest of these three divisions, includes the territory now comprehended in the 19 governments of Archangel, Olonetz, Vologda, Novgorod, Tver, Jaroslav, Kostroma, Pskov, Smolensk (partly), Moscow, Vladimir, Nijni-Novgorod, Kalouga, Toula, Riazan, Tambov, Orel, Koursk, and Voronetz; and is bounded by Finland, the Baltic Provinces, and White Russia on the W., and by the governments now formed out of the old Tartar khanates of Kazan and Astrakhan

on the E.—*White Russia* included the provinces of Vitebsk, Mohilev, and the rest of Smolensk, and though long held by the Poles, was finally re-united to Russia at the first and second partitions of Poland (1772 and 1793). At the latter period, it also received the accession of the Polish provinces of *Black Russia*, or Minsk, *Samogitia*, the rest of *Lithuania* (q. v.), *Podlesia*, *Volhynia*, *Podolia*, and *Polish Ukraine* (now Vilna, Minsk, Kovno, Volhynia, Podolsk), and White Russia with these accessions was then denominated *West Russia*.—*Little Russia* contains the ancient Russian possessions in the south-west, which, in the middle ages, became independent under the Cossacks of the Ukraine, and were finally reunited to Russia in 1654; and is divided into the four provinces of Kiev, Tchernigov, Poltava, and Kharkov. During the 18th c., the countries wrested from the Turks, lying between Great Russia and the Black Sea, were formed into a fourth great division, under the name of *Southern Russia*. This last includes the districts occupied by the Don Cossacks, sometimes called *New Russia*.—*Red Russia* was a portion of the Russian principality of Galich (Galicia), and with the rest of it, was subdued by Casimir III. of Poland; it included what is now the province of Lublin, in the kingdom of Poland, and the eastern portion of Austrian Galicia, between Lublin and the Carpathian Mountains, and is inhabited by Poles, and another and antagonistic people, who are called indifferently Red Russians, Russniaks, and *Ruthenes*.

RU'TÉ, a town of Spain, in the province of Cordova, and 43 miles south-east from Cordova, on an affluent of the Jenil. Pop. 8000.

RUVIGADO, a town of the Granadian Confederation, South America, in the department of Cundinamarca, in a mountainous district, on one of the head-waters of the Magdalena, in N. lat. 6° 10', and W. long. 75° 42'. It is 8901 feet above the sea. The chief importance of the town is as a centre of trade for a large neighbourhood. Pop. 10,000.

S

SARLOUIS, a town of Rhenish Prussia, 31 miles south-south-east from Treves, and between four and five miles from the frontier of France. It stands on the left bank of the Saar, a branch of the Moselle, and is a place of some strength, being walled, and containing several forts. It is of considerable importance as a border fortress. There are manufactures of firearms in the town, and lead and iron mines in the neighbourhood. There are also wire-works. S. was long in the possession of France, and was fortified by Vauban in the reign of Louis XIV. The Congress of Vienna gave it to Prussia in 1815. Pop. (1864) 7491.

SA'GUA-LA-GRANDE, a town of Cuba, on the river Sagua, about 12 miles from its mouth, which is on the north coast of the island. It is a town of considerable importance, and is connected by railway with Villa Clara and other places. Pop. (1861) 9632.

SAGUENAY, a large river of Canada, falling into the estuary of the St Lawrence, on the north side, about 115 miles below Quebec. It drains the Lake of St John, which is nearly circular, and almost 30 miles in diameter. Its course from that lake to the Gulf of St Lawrence is about 100 miles, and is almost a straight line. It flows between precipitous cliffs, has numerous cataracts in its upper part, and is in many places two or three miles broad. In the lower part of its course, it is less wide, but very deep, and large ships ascend it more than 60 miles to load with timber from the settlements on its banks. The name S. is sometimes also given to the principal river which falls into Lake St John, and which is known to the Indians as the Chomouchouan and as the Assouapmousoin. It rises about 200 miles to the west of Lake St John, in a region of lakes and marshes.

SAHARANPUR, or **SUHURUNPUR**, a town of British India, North-west Provinces, the chief place of a district of the same name. It is situated

in a plain in N. lat. 29° 58', and E. long 77° 36', about one mile east of the Doab Canal. It has a large fort, a military cantonment, and a government dépôt. S. is about 1000 feet above the sea, and the climate is temperate during great part of the year. S. was therefore chosen as a suitable situation for a botanic garden, for plants requiring a milder climate than that of Calcutta, and one was formed in 1817. S. is described as one of the most handsome British stations in India. Pop. about 38,000.

ST ALBAN HALL, OXFORD, takes its name from Robert de St Alban, a citizen of Oxford, who conveyed the building to the nuns of Littlemore, near Oxford, in 1230. On the dissolution of the nunnery, it was given by King Henry VIII to his physician, George Owen, D.M., who conveyed it to Lord Williams of Thame, and Sir John Gresham. By their assignees, it was finally transferred to the Warden and Fellows of Merton College, and was some time after established as an academical Hall. It is the least important of the public halls in the university, having only (1866) 10 members of convocation, and 47 on the books.

ST DOMINGO. In 1865, Spain relinquished this possession, which is again an independent republic.

SAINTE-BEUVE, CHARLES-AUGUSTIN, a French poet and critic of great eminence, was born at Boulogne-sur-Mer, on 23d December 1804. His father, who died two months before his birth, was *principal des droits réunis* at that port. His mother, a woman of superior character and intelligence, was by family originally English, and through her the boy early acquired a familiarity with the English language and literature. He was educated at an institution of his native place, and afterwards at the College Charlemagne in Paris. On leaving college, though his bent towards literature was already pronounced, he was shy of committing himself to it as a profession, and betook himself to the study of medicine and anatomy. Shortly, he obtained a situation at the Hospital St Louis. Here for some time he worked steadily; but his spare time was occupied with literature; and his articles contributed to the *Globe* on topics of history, philosophy, and criticism, attracted attention, and in particular procured him the acquaintance of the celebrated M. Jouffroy. While he was thus wavering between literature and the claims of a profession distasteful to him, Victor Hugo's *Odes et Ballades* were published, and the impression made upon him by this work, of which he wrote an enthusiastic *critique*, seems to have determined him finally to a life exclusively literary. He gave up his situation at the hospital, and attached himself to *Le Cénacle*, along with Alfred de Musset, the two Deschamps, and others of the so-called Romantic School. Shortly, he gave to the world his *Tableau Historique et Critique de la Poésie Française, au XVI. Siècle* (1828—afterwards enlarged in ed. 1843), which at once established his reputation as one of the first critics of the time. His next work, *Les Poésies de Joseph Delorme*, though somewhat coolly received by the public, brought him what perhaps pleased him better than any applause of the multitude, the emphatic approval of Béranger and others of the literary guild. *Les Consolations*, published in 1830, was considerably more successful in hitting the taste of the public. On the cessation of *Le Cénacle*, after the revolution of 1830, S. attached himself to the *Globe*; and subsequently, he wrote much in the *Revue des Deux Mondes*, the *National*, and the *Constitutionnel*. In 1834, appeared his *Volupté*, a work curious as a study of moral

pathology, but more curious than pleasing; and in 1840, he published the first volume of his *Histoire de Port Royal*, a work which, in 1860, he completed in five volumes. On 27th February 1845, he received the most distinguished mark of honour which can fall to a Frenchman of letters, by his election to be a member of the Academy. In 1850, he began to issue, in the pages of the *Constitutionnel*, the famous series entitled *Causeries de Lundi*, the most delightful of all his works, and that by which he is most widely known. After the *coup d'état* of 2d December 1851, he became connected with the *Moniteur*, and was appointed Professor of Latin Poetry at the Collège de France. Of this appointment some fruits are before the world in his *L'Etude sur Virgile*, published in 1857. In 1865, he was called to be a member of the Senate.

As a poet, S., despite the fine talent he displayed, never succeeded in becoming popular, nor can very high rank be accorded him. But as critic, he was 'himself alone,' and his place is by common consent in the very fore-front of French literature. His sympathies were wide and catholic; in delicacy of perception, and subtlety of refined analysis, he was almost without a rival; his style is piquant, lively, fascinating, instinct with individual expressiveness; and nothing can exceed the felicity with which the interest of criticism proper is combined in his sketches with that of anecdotic biography.

Of his works not already glanced at, the following only need be mentioned: *Poésies Complètes* (1840, 12mo); *Critiques et Portraits Littéraires* (1832—1839, 5 vols. 8vo); *Portraits Littéraires* (1844, 2 vols. 12mo); *Portraits Contemporains* (2 vols. 12mo); *Causeries de Lundi* (1851—1857, vols. 1—13, 12mo); *Nouveaux Lundis* (1863, vols. 1—11, 18mo); not to mention an immense mass of miscellaneous work. He died November 1869.

SAINTE-CLAIRE DEVILLE, HENRI ETIENNE, French chemist, was born in March 1818, at St Thomas, West Indies, and was educated in France. On quitting college, he constructed at his own cost a chemical laboratory, and for nine years, without master and without pupils, devoted himself to patient studies and skilful researches. In 1844, he was commissioned to organise the Faculty of Sciences of Besançon, of which, in the following year, he was appointed Dean and Professor. In 1851, he succeeded M. Balard in the chair of Chemistry in the Ecole Normale. Since 1853, he has supplied the place of M. Dumas in the Faculty of Sciences of Paris. In 1861, he was chosen a member of the Academy of Sciences of the Institute, in place of M. Berthier in the section of Mineralogy.

S. D.'s earliest investigations relate to different essences and resins, and the most important are in the department of mineral chemistry. In 1849, he made known the mode of preparation and the properties of anhydrous nitric acid, a compound whose existence had been up to that date ignored. In 1852, he published an important paper on Metallic Carbonates and their Combinations; and in the following year, a new method of mineral analysis, known as the middle way, in which he proposes the exclusive employment of gases and volatile re-agents, against the errors arising from the use of the filter.

About the same time, he began his researches into aluminium, a metal discovered in 1827 by Wohler of Göttingen, but still very imperfectly known, and set forth its special properties. Being commissioned by the emperor to inquire as to the best method of obtaining aluminium at a low price, he made numerous experiments, jointly with M. Debray, in the factory at Javel; and after some

months, succeeded in producing ingots of the metal, which were shewn in the Exposition Universelle of 1855. These experiments, and the properties of aluminium, have been described by S. D. in scientific periodicals; and among his later papers are—on the Three Molecular States of Silicium; on the Metallurgy of Platina; on the Density of Vapours at very High Temperatures; on the Measurement of High Temperatures; on the Permeability of Iron to Gases at a High Temperature; on the Phenomena of Dissociation in Homogeneous Flames; and on the Industrial Preparation of Aluminium and its Compounds. These papers are published in the *Mémoires* and *Comptes Rendus* of the Académie des Sciences de l'Institut, and in the *Annales de Chimie et de Physique*.

SAINTE MARIE-AUX-MINES (Ger. *Maria-kirch*), a town of France, in the dep. of Haut-Rhin, on the Liepvrette, 12 miles north-west of Colmar, at the foot of the Vosges Mountains. It formerly owed its prosperity to its silver mines, but these are no longer worked. Its chief manufactures are cotton fabrics of various kinds, paper, and cherry-brandy. Pop. (1866) 8314.

SAINT LOUIS, the capital of the French possessions in Senegambia, is situated on a small low island of the same name, at the mouth of the Senegal river. The town covers almost the whole island. With its fortifications, it presents an imposing appearance from the sea, but the interior is mean and dirty. The harbour is good. The principal building is the government house. There are 600 stores for goods. Saint L. possesses a botanic garden, founded in 1822. Pop. (1861) 17,600.

SAINT PIERRE, a town of the island of Bourbon (q. v.), or Réunion, on the south-west coast, 34 miles south-west from Saint Denis. Pop. 14,135.

SAINT-PIERRE-LÈS-CALAIS, a town of France, in the dep. of Pas-de-Calais. It may almost be regarded as a south-eastern suburb of Calais, to which it nearly adjoins, but has grown to a size exceeding that of Calais itself. It is famous for its manufactures of Tulle (q. v.). Other branches of industry are also actively prosecuted, as the manufactures of leather and beetroot sugar. Pop. (1866) 14,942.

SALEMI, a town of Sicily, in the province of Trapani, 39 miles south-west from Palermo. Pop. (1861) 11,340.

SALINS (anc. *Salinae*), a town of the dep. of Jura, France, 52 miles north-by-west from Geneva, on the Furieuse, a feeder of the Doubs. It is situated in a narrow rocky gorge between two lofty hills, looking upon a fertile and beautiful valley. It derives its importance from its salt-works, from which also it has its name. The salt is obtained from brine-springs, and the evaporation of the brine is mostly carried on in a great building, in the valley below the town, which has long borne the name of the *Salines Royales*; but that of the weaker springs is conveyed in pipes to the forest of Chauv, 15 miles off, where it is first slowly evaporated in *maisons de graduation*, and afterwards by boiling. There are iron-works, soda-factories, tanneries, and quarries of gypsum in S. and its immediate neighbourhood. Pop. (1866) 5556.

SALLEE, or **SLA**, a seaport town of Morocco, in the territory and former kingdom of Fez, 106 miles west from Fez. It stands on a low sandy point of the shore of the Atlantic, at the mouth of the Bu-Regreb, on the northern side of the river, whilst opposite to it, on the southern side, is the town of Rabat. Both S. and Rabat were bombarded and

nearly destroyed by the French in 1851. S. was in former centuries noted as a haunt of pirates, and a *Sallee Rover* was the dread of peaceful mariners in the Atlantic and Mediterranean. It is particularly noted for the carpets which it produces, of fine texture and bright colours. They are mostly used in Morocco itself. The chief export from S. is wool. Pop. estimated at about 12,000, of whom 3000 are Jews.

SALMON OF NORTH-WESTERN AMERICA. The rivers of North-western America abound in salmon and trout to a degree not exceeded, and perhaps not equalled, in any other part of the world. Since the article SALMON was written, a very interesting account of the most important species has been given by Mr J. K. Lord, in his work entitled *The Naturalist in Vancouver Island and British Columbia* (2 vols., Lond. 1866), to which we are indebted also for accounts of the Candle-fish, Vancouver Island Herring, and Viviparous Fish, noticed in this Supplement. The first place must be given to *Salmo Quinmat*, of which Quinmat is one of the Indian names, a fish similar in quality to our European salmon, and sometimes 70 lbs. in weight. It is very thick in proportion to its length, the dorsal outline slightly arched, almost forming a notch with the tail. The back is light steel blue, shading to a lighter tint on the sides, and imperceptibly changing to gray or silvery white, blushed over with pink, on the belly. The upper parts, and often also the lower, are thickly spotted with black stars. Salmon of this species ascend the Columbia, the Fraser, and other rivers in prodigious numbers, at the spawning season, and proceed hundreds of miles, and even in the Columbia 1000 miles, from the sea into every rivulet, 'filling even pools left on the prairies and flats by the receding floods.' In what multitudes they crowd up the rivers will be even better understood from the following statements of Mr Lord, relating to a tributary of the Fraser. 'About a mile from my camp was a large patch of pebbly ground, through which a shallow stream found its way into the larger river. Though barely of sufficient depth to cover an ordinary-sized salmon, yet I have seen that stream so filled, that fish pushed one another out of the water high and dry upon the pebbles. . . . With one's hands only, or more easily, by employing a gaff or crook-stick, tons of salmon could have been procured by the simple process of hooking them out.' Mr Lord goes on to express his opinion that thousands of the salmon ascending the small mountain-streams never can spawn from sheer want of room. He describes them as dying by scores at the base of a waterfall which they could not leap, where, however, they persisted in remaining till they died from inanition, fresh fish coming up as the dead ones floated down. A prodigious stench arises from the multitudes of dead salmon floated down the rivers. The Indians say that all the salmon of this species that come up to spawn die in the rivers; and Mr Lord believes that few, if any, ever reach the sea again. They seem not to eat when in the fresh water, and cannot be tempted either by fly or bait, nor is any food to be found in their stomachs, although, in the stomachs of those taken in the tideway or salt water, the remains of small fish and marine animals are to be found. This kind of salmon ascends the rivers in June and July, for, unlike the salmon of Britain, it spawns in summer.—At the same time with *Salmo Quinmat*, a smaller species, called by the Indians, at the Kettle Falls, the Cha-la-lool (*Salmo Gairdneri*), ascends the rivers. Its average weight is only from eight to eleven pounds, but when it first arrives in the fresh water, its flesh is fat, pink, firm, and most

delicious.—A little later in the season, comes the WEAK-TOOTHED SALMON (*Salmo paucidens*).—The autumn, also, has its supply of salmon, quite equal to that of spring in point of numbers, but inferior in quality. They ascend the rivers in September and October. The autumnal salmon (*Salmo lycaodon* of Pallas), a species known also in Northern Asia, is a dingy hook-nosed fish, called *Hooked Snout* by the fur-traders. The hooked snout, however, is peculiar to the males. Salmon of this species are to be found 'in every stream and rill where they can by any possibility work a passage,' and they often remain in fresh water, far from the sea, for four or six months, all of them becoming emaciated, and many of them dying, whilst the snout of the male becomes prodigiously elongated, and the teeth also increase into tusks. As to the multitudes of the full-grown fish of this species to be found at the proper season in the rivers of North-western America, the following extract from Mr Lord's book is conclusive. 'At Fort Hope, on the Fraser River, in the month of September, I was going trout-fishing in a beautiful stream, the Quaque-alla, that comes thundering and dancing down the Cascade Mountains, cold and clear as crystal; these salmon were then toiling up in thousands, and were so thick in the ford that I had great trouble to ride my horse through: the salmon were in such numbers about his legs as to impede his progress, and frightened him so that he plunged viciously, and very nearly had me off.'—The RED-SPOTTED SALMON TROUT (*Salmo spectabilis*) is another valuable fish of the same regions. It seldom exceeds three pounds in weight. It ascends the rivers in October, when a great Indian fish-harvest takes place. This fish is readily taken by hooks baited with dried salmon-roe, or by a small shining strip from the belly of a trout.—The OREGON BROOK TROUT (*Salmo* or *Fario stellatus*) abounds in the rivers and streams of North-western America, even to a height of 7000 feet in the Rocky Mountains. It attains a weight of three pounds, and is a delicious fish. This trout is readily taken with fly or bait.

The Indians of these regions take the salmon, as they ascend the rivers, by various contrivances. They construct weirs reaching from one side of a stream to the other, with openings, through which the fish pass into large lateral prisons of closely woven wicker. They use nets in the bays and harbours, when the salmon, pursuing anchovies and herrings, run into the net, and are caught, and thus immense numbers are taken. They construct rude scaffolds or stages of wood among the boulders on the sides of large rivers, on each of which many Indian fishers await the salmon, with small nets fastened to handles, forty or fifty feet in length. Thirty salmon an hour is not an unusual take for two Indians to land on a stage. Another and more curious method, practised at falls, is by means of great wicker hampers, about 30 feet in circumference, and 12 feet in depth. To make these available, huge trees are cut down, lopped clear of their branches, and brought to the edge of the river, where they are fastened so that the smaller ends overhang the foaming water. To these the wicker baskets are suspended, where the salmon generally leap in their attempt to clear the falls; and in each basket two naked Indians are stationed all day, frequent relays being necessary, as they are under a heavy fall of water. As the salmon fall into the basket, the Indians catch them under the gills, kill them with a club, and fling them on the rocks. Mr Lord says: 'I have known 300 salmon landed from one basket between sunrise and sunset, varying in weight from 20 to 75 lbs.' The salmon and trout of these regions will probably soon be

brought in some form or other to the markets of the more densely peopled parts of the world.

SAMBOR, New, a town of the Austrian Empire, in the province of East Galicia, the capital of a circle, on the left bank of the Dniester, 44 miles south-west from Lemberg. It is a thriving and well-built town, with manufactures of linens and extensive salt-works. Pop. 10,500.

SANDHURST, a town of Victoria, 82 miles north-north-west from Melbourne, on the railway between Melbourne and Ebuca. It is the centre of an important mining district of the Bendigo gold-fields. Pop. (1861) about 11,000. In the district of S., there are many Chinese.

SAN FELÉ, a town of South Italy, in the province of Potenza, 17 miles north-west from Potenza, among the Apennines, on one of the head-waters of the Ofanto. It has an ancient castle. Pop. 9086.

SAN FRATELLO, a town of Sicily, in the province of Messina, 53 miles west-south-west from Messina. It stands on a height, about five miles from the sea. At the base of the hill on which the town stands is a remarkable cave, discovered in 1859, and containing prodigious quantities of bones of mammals, with which flint implements are mixed. Pop. 7200.

SANITARY SCIENCE, known also under the names of PREVENTIVE MEDICINE, STATE MEDICINE, HYGIENE, and PUBLIC HEALTH, has been variously defined by different writers. Dr Mapother's is perhaps as good a definition as any. In the first of his *Lectures on Public Health*, he describes this science as 'an application of the laws of physiology and general pathology to the maintenance of the health and life of communities, by means of those agencies which are in common and constant use.' This department of science received so strong an impulse, about a quarter of a century ago, from the labours of Southwood Smith, Edwin Chadwick, Lyon Playfair, and others, that many persons regard it as of modern origin; and doubtless to a great extent they are right; but on turning back to the records of early history, we almost invariably find evidence that the health of the general population was a subject of legislation. The Mosaic code of laws—the most ancient on record—contains minute directions for the cleanliness of the person, the purification of the dwelling and the camp, the selection of healthy and the avoidance of unwholesome food (pork, for example, which in hot countries is more commonly found to harbour parasites than in temperate climates, and blood, which is the most putrescible part of the animal), the seclusion of persons with contagious disorders, the regulation of sexual intercourse at certain periods, and various other points bearing on the physical well-being of the Jewish nation. The Greeks and Romans, although not, like the Jews, making hygiene a part of their religious duties, were far from neglecting it. 'The Laws of Lycurgus,' says Dr Gairdner, 'are not wanting in very pointed enactments on sanitary matters; and the importance attached by all the Greek republics, and in the Platonic ideal polity, to physical culture, is too well known to require remark. The Roman people, poor and apparently rude as it was in its origin, yet found time, amidst its military occupations, to construct the *Cloaca Maxima*, as an indestructible and stupendous memorial of its attention to the drainage and sewerage of the city at a very early period of its history. At a later period, aqueducts were made to cover miles upon miles of the surrounding plain; and their splendid ruins, still partly used for their original purpose, attest the munificence and the abundance with which the first of sanitary requisites was supplied

to the imperial city.'—*Public Health in Relation to Air and Water*, 1862, p. 6. Moreover, we know enough of the construction of the private houses and public buildings of the Romans to see that they recognised the necessity for free ventilation and good drainage. When the *Archiatri populares*, or state-physicians, were first appointed in the Roman Empire, is not certainly known. Their mode of election is described in the Theodosian and Justinian codes. There were ten of them in the largest towns; one to each district or subdivision; seven in towns of the second order; and five in the smaller ones. They collectively formed a college, whose duty it was to attend to the public health; and they may be regarded as the earliest type of our 'General Medical Council.' Gradually, however, as Christianity spread, an utter misconception of doctrine led to the neglect of all care of the human body. While the monks and friars devoted themselves to good works, feeding the hungry, clothing the naked, and instituting hospitals, they entertained no idea of the possible prevention of disease. They never attempted to impress upon their followers the importance of drainage, ventilation, pure and abundant water, &c.; but when an epidemic arose, it was supposed to be a manifestation of God's special anger; and it would have been impossible to make them understand that it was the natural result of a prolonged disregard of the laws of nature. Those who have read Dean Stanley's graphic *Memorials of Thomas A'Becket* will be inclined to wonder whether those who adopted such penances as his could ever be free from cutaneous disorders. The state of the towns in England in the 13th c. is so clearly described by Mr Brewer in his Introduction to the *Monumenta Francicana*, that we should have been glad to have extracted it, if our space had permitted. Those who have not access to the valuable series in which Mr Brewer's work is included, will find a sufficient quotation from it in Dr Gairdner's interesting volume on *Air and Water*, pp. 44—47. In another work in the same series—the *Liber Albus*, edited by Mr Riley—much important information regarding the general sanitary state of London in the mediæval times may also be found. In addition to the causes of disease indicated by these writers, such as the absence of drainage, the accumulation of filth, bad ventilation, insufficient and often unwholesome water, inattention to personal cleanliness, &c., must also be noticed the ordinary food in those times. The common vegetables of our own day, excepting the cabbage, were only slowly introduced from the time of Henry VIII. As turnips were not then used as a winter-food for oxen and sheep, these animals were with difficulty kept alive during the season when grass was scanty, and were therefore killed and salted in the beginning of the cold weather; and during several months, game and river-fish were the only kinds of fresh animal food. Macaulay, in his celebrated third chapter on 'The State of England in 1685,' observes that, at that time, meat, although cheaper than in former times, was still so dear that hundreds of thousands of families scarcely knew the taste of it; that bread such as is now given to the inmates of work-houses was then seldom seen even on the trencher of a yeoman or of a shopkeeper; and that the great majority of the natives lived almost entirely on rye, barley, and oats. Many important facts of a similar nature are also recorded in Froude's *History of England*.

During the 18th c., many important steps were taken for the improvement of the public health. Under a proper system of drainage, ague became eradicated from extensive fenny districts; and with a knowledge of the therapeutic properties of

cinchona bark and arsenic, we can cut short the disease when it appears. Scurvy* was all but blotted out of the list of diseases that proved most fatal to our sailors; and vaccination, incomparably the greatest discovery yet made in this department of science, was the crowning achievement of the century.† The first outbreak of cholera in this country in 1832, lamentable as it was in itself, was productive of much benefit in directing the public mind to the all-important subject of the prevention or repression of disease. It was impossible to ignore the fact that, while the poor, dwelling in unventilated and undrained hovels, fell victims to this new and ill-understood disease in thousands, the middle and higher classes were comparatively safe. All investigations into the dwellings and domestic habits of the lowest class of the population revealed a condition of things of which the general public had no conception. A new poor-law was consequently passed in 1834, and a commission was appointed to investigate and report upon its working. The *Report on the Sanitary Condition of the Labouring Population of Great Britain*, published in 1842, and mainly treating of the sanitary state of the poor and of the character of their dwellings, may be regarded, as Professor Gairdner‡ well observes, as 'the true starting-point of modern sanitary legislation.' A 'Health of Towns' Commission, which was soon after appointed, gave in two valuable Reports in 1844 and 1845; and subsequently, a Metropolitan Sanitary Commission published Reports in the years 1847 and 1848. These Reports will form a lasting memorial of the labours of Mr Chadwick and his able co-operators. Nor, in this rapid glance at the history of sanitary science, can the name of Dr William Farr be omitted, who—again to quote Dr Gairdner's words—found the facts of this science in a state of almost hopeless and aimless confusion, and has not only added immensely to their number and value, but has brought into them light, harmony, order, and, for the first time in the history of the science, a determinate method, and an approach to scientific exactness.' By his system of calculating death-rates, he has placed an easy and useful method at the service of his professional brethren, while, by the formation of life-tables, he has greatly facilitated the operations of life-assurance.

We now pass on to the consideration of the most important sanitary agents, beginning with AIR. Under this head, we have to consider (1) the amount of air necessary for the full performance of the respiratory process; (2) the means of ascertaining when air is impure, or, if impure, what substances are mixed with it; (3) the means of purifying contaminated air; and (4) the diseases due to deficiency in the quantity, and alterations in the quality of the air.

(1) The first question can be answered both by calculation and experiment. By calculation, Dr Parkes finds that 2082 cubic feet of air must be supplied per head per hour, so to dilute the products

* We regret to state that during the last few years scurvy is again becoming prevalent in the mercantile service, and occasionally amongst navvies engaged at places where good food was not easily attainable. In both cases, it may always be traced to neglect of due dietetic precautions.

† And yet, in consequence of vaccination being either neglected or imperfectly performed, no less than 51,034 persons died in Great Britain from small-pox in the ten years, 1856—1865. In the year 1864 alone, the deaths were 9425. On this subject, see Sir James Y. Simpson's 'Proposal to stamp out Small-pox, &c.,' in the *Medical Times and Gazette* for January 4, 1868.

‡ *Public Health in Relation to Air and Water*, p. 17.

of respiration and transpiration from the sound body, as to keep the air always pure and fresh (see his *Manual of Practical Hygiene*, 1864, p. 65). From numerous experiments in which the outflow of air was measured, and the carbonic acid simultaneously determined, he found that at least 2000 cubic feet per hour must be given to keep the carbonic acid at its normal level of '5 or '6 in 1000 volumes, and to remove the *odor humanus* or fetid smell of animal matter. General Morin, in his *Rapport de la Commission sur le Chauffage et la Ventilation des Bâtimens du Palais de Justice*, 1860, gives results in close accordance with those of Parkes, assigning the following as the relative hourly amounts of fresh air (expressed in cubic feet) per head in temperate climates: in barracks, at 1059 by day, and 2118 by night; in workshops, prisons, and theatres, 2118; in schools, 1059; and in hospitals, 2825, increased to 4236 during the hours of dressing the surgical cases, and 5650 during epidemics.* In mines, if it is wished to keep up the greatest energies of the men, 6000 feet of air per hour must be allowed. It may be incidentally mentioned that a horse requires 2460 feet per hour at the least. It is difficult to lay down any rules regarding the amount of fresh air required in sickness. The vitiation of the air by the products of combustion of gas, candles, lamps, &c., must not be overlooked. For every cubic foot of gas that is burned, 1800 cubic feet of air are required to keep the air pure, unless the gaseous products are carried off in a special channel, such as is now frequently attached to gas-fittings. A pound of oil burned in a lamp may be regarded as equivalent to 10 cubic feet of gas, so far as the deterioration of the air is concerned. (For these facts, we are indebted to Dr Parkes.)

(2) The composition of pure air is sufficiently described in ATMOSPHERE. The impurities in air may be divided into: (a) suspended matters, (b) gaseous substances, and (c) special impurities. Amongst *suspended matters* are, according to Pasteur and others, numerous and universal germs of organic beings, both animal and vegetable, as of vibriones, bacteria, and monads; pollen, spores of fungi, mycodermis, mucodones, &c. Minute particles of finely comminuted inorganic matter are also often taken up by currents of air, and remain in suspension. These are probably altogether harmless. The works of man more seriously affect the air in a hygienic point of view. Particles of coal and of half-burned carbon (smuts), starch-cells (from bakeries and bread), and, when certain trades are carried on, cotton fibres, hairy particles of wool, of stone, of iron, &c., may, when constantly inhaled, give rise to the production of special diseases of the lungs and stomach. In the air of badly-kept hospital wards, pus-cells and epithelial cells are often to be detected. Most physicians now believe that the specific poisons of small-pox, scarlet fever, and measles, which are derived from the skin and mucous membrane, consist of molecular organic matter, which, although as yet undetected, must pass into the air; and the same remark applies to the so-called germs of typhoid fever (see the article on TYPHUS AND TYPHOID FEVERS) and cholera, which are thrown off by the intestinal mucous membrane, and subsequently become dried and capable of aerial suspension. Amongst *gaseous matters*, which merely pass into the atmosphere either from natural causes or manufactories, are various compounds of carbon, sulphur, chlorine,

nitrogen, and phosphorus, with oxygen and hydrogen, which it is unnecessary here to enumerate. Besides the gases formed by the union of the above-named elements, we must notice organic vapour from decomposing animal matters and sewers, which last has been found by Odling to be carbo-ammoniacal. Amongst *special impurities*, those caused by respiration are the most important. An adult man, under ordinary conditions, gives off, in 24 hours, from 12 to 16 cubic feet of carbonic acid by the lungs, and a certain additional quantity, not determined, by the skin. Watery vapour, ranging from 25 to 40 ounces, also passes off daily from the skin and lungs, together with an undetermined quantity of organic matter, which is partly suspended (as particles of epithelium, &c.), and partly made up of organic vapour. This vapour, when collected and condensed from a large volume of respired air, is found to be nitrogenous, and has a very fetid smell. Here there is a most powerful source of vitiation, regarding which numerous chemical analyses have been made; for details regarding which we may refer to Parkes, *op. cit.* pp. 70—77; Gairdner, *op. cit.* p. 69; and Mapother's *Lectures on Public Health*, 2d ed., pp. 40—81. There is a condition of the atmosphere to which various observers, and especially Pasteur, have directed attention, which requires a passing remark. It is what may be termed the fermentative condition, and depends upon the universal presence in the air of countless germs of vegetables and infusoria. It is possible that this atmospheric condition may be concerned in some of the zymotic diseases. Dr Salisbury, an American physician, endeavours to shew that the poison of measles is due to a fungus which grows on rotten straw; another American physician, Dr Flint, has almost fully demonstrated that the spores of palmella cause ague.—Mapother, *op. cit.*, p. 431, &c. The presence of a *cholera-fungus*, which has been recently proved to exist in the evacuations of all cholera patients, gives, as will be seen from Mr Simon's Report of the Weimar Conference,* a hint as to the probable cause of that disease. Bearing on the same subject is the fact, lately noticed by Davaine, that the splenic apoplexy of sheep is owing to the presence of bacteria in the blood, and that sheep, rabbits, and horses can be inoculated by transferring into their circulation the bacteria, which are extremely thin rod-like organisms, varying in length from $\frac{1}{1000}$ th to $\frac{1}{500}$ th of an inch. The same observer has just found (as we learn from the 'Parisian Medical Intelligence,' in the *Lancet* for January 4, 1868) that bacteria are to be found in all carbuncular diseases of any form whatever; that the supervention of these little beings in the spleen, the lungs, and the blood, precedes the occurrence of morbid phenomena; and that the carbuncular blood ceases to be contagious as soon as the bacteria have disappeared; and hence he feels justified in regarding them as the cause of carbuncle. Another French observer, M. Poulet, has just detected myriads of infusoria (*monas termo* and others) in the breath exhaled in whooping-cough. If one contagious disease can be proved to be connected with the germs occurring in the air, it is almost a certainty that similar diseases must arise from corresponding causes.

(3) The natural means of purifying the atmosphere are diffusion, oxidation, the action of winds, and the fall of rain. In cases where the air is specially impure, as in sick-rooms where there are contagious cases, the agents commonly known as *Disinfectants* (q. v.), or *deodorants*, are employed. Amongst the

* The older observers fixed the necessary quantity of fresh air far too low: Pelet thought 212 feet sufficient; Arago 353 feet; and Dr Reid, 600 feet per hour.

* *Ninth Report of the Medical Officer of the Prussian Council* (1866), pages 29 and 515.

solids of this class are charcoal (see WOOD-CHARCOAL), dried earth, and the carbonates of lime and magnesia. Amongst the *liquids*, those in highest reputation are *Condy's Fluid** (consisting of an alkaline permanganate, which at once decomposes ammoniacal compounds, and destroys organic matter rapidly) and carbonic acid: whilst amongst the *gases* or *vapours*—which are the most powerful means of purifying the atmosphere, next to ventilation—may be especially mentioned chlorine, nitrous acid, and sulphurous acid; of these, says Dr Parkes, the nitrous acid is probably the most powerful, but it is useful to employ all three alternately, or even together. It must be recollected that all these agents are mere auxiliaries to ventilation, the primary importance of which must never be forgotten.

(4) Abundant experience confirms the view which might have been *a priori* inferred from the study of the physiology of Respiration (q. v.), that the breathing of impure air must be incompatible with perfect health. The special impurities which are worthy of notice as being causes of disease, or of an impaired state of health, are arranged by Dr Parkes as follows: (a) Suspended matters; (b) Gaseous matters; (c) Impurities from several substances always co-existing.

(a) *The suspended matters* which are known to occasion disease in various trades, are very numerous. Thackrah, in his well-known work on *The Effects of Arts, Trades, and Professions on Health*, published in 1832, gives the following list of workmen who were injuriously affected by the dust of their trades: Corn-millers, maltsters, tea-men, coffee-roasters, snuff-makers, paper-makers, flock-dressers, feather-dressers, shoddy-grinders, weavers of coverlets, weavers of harding, dressers of hair, hatters employed in the bowing department, dressers of coloured leather, workers in flax, dressers of hemp, some workers in wood, ware-grinders, masons, colliers, iron-miners, lead-miners, grinders of metals, file-cutters, machine-makers, makers of firearms, and button-makers. To this list must be added colliers, who suffer from lung-disease in ill-ventilated mines; potters, especially the class called *flat-pressers*, in whom emphysema is so common that it is known as 'the potters' asthma;' the china-scourers, who all, sooner or later, become asthmatical from inhaling the light flint-dust in suspension; pearl button-makers and pin-pointers, who suffer from bronchitis and hæmoptysis; the makers of grinding-stones; the makers of Portland cement, &c. In some trades, irritant vapours are more or less associated with suspended particles in causing disease. Brass-founders suffer not only bronchitis and asthma from the inhaled dust, but also a special disease, described by Dr Greenhow (in the *Proceedings of the Medico-Chirurg. Soc.* vol. 4) as Brassfounders' Ague, which is apparently produced by the inhalation of the fumes of oxide of zinc; the symptoms being oppression of the chest, with indefinite nervous sensations, followed by shivering, a hot stage, and profuse sweating. Coppermiths and tin-plate workers are liable to somewhat similar attacks. Plumbers, house-painters, manufacturers of white-lead, &c., are, as is well known, liable to lead-poisoning. The peculiar affection to which workers in mercury and its amalgams, as silverers and water-gilders, are exposed, is described in the article PARALYSIS, under the name of *Mercurial*

Tremor, or The Trembles. In the various trades in which arsenical compounds are employed, as in making artificial flowers, green paper for walls, &c., preparing arsenical pigments, &c., the well-known symptoms of chronic arsenical poisoning are likely to ensue. On the subject, Dr Guy has, at the request of government, drawn up an elaborate Report.

Passing from inorganic or unorganised matter to organic substances floating in the atmosphere, and giving rise to a large class of important diseases, we may remark, that it still remains to be decided in what exact condition this organic matter exists—whether it is in the form of impalpable particles, or moist or dry epithelial or pus cells; 'and whether it is always contained in the substances discharged or thrown off from the body (as is certainly the case in small-pox), or is produced by putrefactive changes in these discharges, as is supposed to be the case in cholera and dysentery, is also a matter of doubt. But, from the way in which, in many cases, the organic substance is absorbed by hygroscopic substances, it appears that it is often combined, or at anyrate condensed, with the water of the atmosphere.'—Parke, *op. cit.*, p. 86. This much is known with certainty regarding the specific poisons—viz., that they differ extremely in the readiness with which they are oxidised and rendered harmless. While typhus and oriental plague throw off a poison, which, if there is due ventilation, is readily destroyed, the poisons of small-pox and scarlatina spread in defiance of free ventilation, and retain their virulence for weeks or months.

(b) The most important *gaseous matters* in the air likely to produce disease are *carbonic acid* and *carbonic oxide*. The normal quantity of carbonic acid in the air being regarded as '5 in 1000 volumes, 'it produces fatal results when the amount reaches 50 per 1000 volumes; and at an amount much below this, 15 or 20 per 1000, it produces in some persons, at anyrate, severe headache.' Dr de Chaumont, assistant Professor of Hygiene at Netley, has published a valuable paper in the *Lancet* for September 1866, in which he shews how the amount of air necessary to reduce the carbonic acid of respiration to a given standard could be calculated; and in the *Edinburgh Medical Journal* for May 1867, he has given extended formulæ for calculating most of the problems connected with ventilation. Amongst the most important of his conclusions are the following: (1) We cannot safely accept a lower standard of purity than '06 per cent. of carbonic acid. (2) Uniform diffusion being supposed, we cannot preserve this standard with a less delivery of fresh air than 3000 cubic feet per head per hour. (3) We must provide an air space which will admit of the delivery of 3000 cubic feet per head, and at the same time preclude the necessity of changing the whole air so often as six times per hour, for which condition a minimum of 1000 cubic feet is absolutely necessary.* *Carbonic Oxide* (q. v.), which is often developed in association with carbonic acid, is far more actively poisonous than carbonic acid. An atmosphere containing $\frac{1}{4}$ per cent. killed small birds in three minutes; and when 1 per cent was present, they died in half this time (Letheby). For the effect of other gaseous matters, as sulphuretted hydrogen, carburetted hydrogen, sulphurous acid gas, hydrochloric acid

* A committee, of which Sir T. Watson was president, recently appointed by the Poor-law Board to consider the question of the amount of cubic space necessary for the sick in workhouse infirmaries, report that for ordinary patients 850, for offensive cases 1200, and for fever patients 2000 cubic feet should be allowed. Although these spaces are greater than we find in most workhouses, it is obvious from the statements in the text that they are not sufficient.

* It may interest some of our readers to know that by washing the cavity of the mouth with a very weak solution of Condy's Fluid, the odour of tobacco is instantly removed.

gas, &c. we must refer to any of the more elaborate works on this subject.

(c) The *impurities from several co-existing agents* next claim attention. In point of fact, these are the impurities with which we have practically almost always to deal, and it is very probable that a knowledge of the actions of two or more isolated noxious agents might lead us to very incorrect conclusions regarding the composite effect that is actually produced. When air is vitiated by respiration, it is popularly believed that the carbonic acid gas is the chief poisonous agent; and that the fatality in such well-known cases as the Black Hole (q. v.) of Calcutta, the prison in which the Austrians were placed after the battle of Austerlitz, the steamer *Londonderry*, &c., is simply due to the action of this gas. The true poisonous agencies in these instances are the organic matter, which is always found in air rendered fetid by the prolonged respiration and cutaneous exhalation of a crowd of human beings, and the deficiency of the oxidation, and the consequent increase of putrescent matter in the body (see Carpenter's *Human Physiology*, 1864, p. 304). Putting aside these extreme cases, which are of rare occurrence, we have abundant evidence in the Reports of the Health of Towns Commission, and elsewhere, that the continuous inhalation of an atmosphere moderately vitiated from respiration has an injurious effect on the health. The aëration of the blood is imperfectly effected, and the nutrition generally is more or less interfered with. Although impure air has long been vaguely regarded as a cause of phthisis, it is only during the present century that the fact has been placed on unquestionable authority. It may now be regarded as established, that not only phthisis but other lung-diseases may have their origin in breathing an atmosphere contaminated by respiration. The subject is one of such vital importance that we shall adduce the very strong evidence of Dr Parkes, who most distinctly proves that the prevalence of phthisis amongst our troops is in a direct ratio to the impurity of the air in the barracks. 'A great amount of phthisis used to prevail,' he observes, 'in the most varied stations of the army, and in the most beautiful climates: in Gibraltar, Malta, Ionia, Jamaica, Trinidad, Bermuda, &c., in all which places the only common condition was the vitiated atmosphere which our barrack-system everywhere produced. And, as if to clench the argument, there has been of late years a most decided decline in phthisical cases in these stations, while the only circumstance which has notably changed in the time has been the condition of the air. So also the extraordinary amount of consumption which prevails in the men of the royal and merchant navies, and which, in some men-of-war, has amounted to a veritable epidemic, is in all probability attributable to the faulty ventilation.'—*Op. cit.*, pp. 91, 92. A considerable amount of evidence in support of this view is afforded by comparative pathology. The extraordinary mortality of phthisis amongst the inhabitants of the old monkey-house in the Zoological Gardens, was found to be due to overcrowding and bad ventilation; and now, in their present airy residence, the inhabitants are no longer prematurely cut off. The overcrowding to which cows in large towns are subjected leads to the great amount of pulmonary disease amongst these animals; while horses, which in the worst stables have more free air than cows, rarely suffer. Not only are pulmonary affections induced by the prolonged respiration of air partially vitiated by organic exhalations, but such an atmosphere seems to favour the spread of several well-known specific diseases, as typhus, plague, small-pox, scarlatina, and measles.

Hitherto, we have simply considered the effect of breathing an atmosphere vitiated by the exhalations given off by persons in ordinary health; if we now pass to the consideration of the air of a crowded hospital-ward, we shall find the organic matter not only more abundant, but at the same time far more noxious. The convalescence of patients is much retarded by their being kept in such an atmosphere (see CONVALESCENT HOSPITALS). When the air has absorbed a certain amount of organic impurity, its respiration is very liable to give rise to erysipelas and hospital gangrene. *Sewers* and old *cesspools*, when opened, give off *sewage-gas* containing carbonic acid, sulphuretted hydrogen, sulphide of ammonium, and putrid organic vapour. A case is given in the first volume of the *Health of Towns Report*, which forcibly illustrates this fact. When a privy connected with a school at Clapham was cleaned out, 23 of the children were seized with violent vomiting and purging, headache, great prostration, and convulsive muscular twitchings; and 2 of them died within 24 hours. Sewer-men are more liable to typhoid and typhus fever than other persons; but night-men and scavengers do not seem liable to any special disease. The effect of diluted sewer-gas, from bad drainage, on the health of the population at large, is a distinct question, into which we have not space to enter, further than to remark that typhoid and diarrhoea are commonly induced by the escape of this gas through our drains and water-closets into our houses. The effects of the impurities arising from manufactories of various kinds, are of course extremely varied; and the subject is so extensive a one that it must be touched upon very briefly. Sulphurous and sulphuric acid are given off from vitriol and copper-smelting works; hydrochloric acid from alkali-works; arsenical fumes and sulphurous acid from copper and lead smelting furnaces; carbonic acid and carbonic oxide from cement-works, &c. Soap and candle manufactories, if not well superintended, yield various gases of a rancid smell, and even that powerful irritant, acroleine. Gas-works in which the wet-lime process of purification is adopted, often evolve sulphuretted hydrogen to such a degree as to become a nuisance injurious to health. Manure-works usually evolve more or less disgusting smells according to the basis operated on, and the mode of preparation. No bad effect on the health has, so far as we know, been observed in this country, from the gases given off by such works, and the exhalations from the manufactories of *poudrette*, which is dry fecal matter, are positively declared, by several of the highest French authorities, to exercise no injurious action either on man or vegetation; but the eminent French hygienist, Parent Duchâtelet, relates two cases in which *poudrette* underwent fermentation on board ship; and in one of these cases, the vessel lost half her crew (number not stated); while in the other, all on board (five) suffered from intense headache, pain in the limbs, vomiting, prostration, and (in two cases) diarrhoea. The *air of old graveyards*, when they are disturbed, often gives rise to epidemics of fever; but the effect of the effluvia of comparatively recent putrefying human bodies is much more decided. Numerous cases are recorded of asphyxia and various forms of fever arising from the exhumation and disturbance of bodies. How far the effluvia arising from *slaughter-houses* and *knackereries* are injurious to health, is an open question. There is very strong general evidence that the men employed at Montfaucon (where, however, the ventilation is excellent, and no putrid matters are allowed to remain) enjoy good health; and Tardien, from a late re-examination of the point, confirms the old conclusion, except so far as glanders and

malignant pustule are concerned. The danger of breathing the *air of marshes* also requires notice. Malaria seems not only to occasion intermittent and remittent fevers, but diarrhoea and pure dysentery. Organic matter to the amount of eight grains has been obtained from 1000 cubic feet of air collected over marshes; and it is worthy of notice that it has just the same chemical characters as the organic matter exhaled from the lungs, turning red with nitrate of silver, yielding ammonia when treated with lime, and blackening sulphuric acid when drawn through it. See Mapother, *op. cit.*, p. 87.

The next point to be considered is the means to be adopted for continually changing the air, so as to keep it in its natural purity. We have already shewn that this change must amount to at least 2000 cubic feet per head per hour for persons in health; and sometimes double that amount, or more, for sick persons. The general principles of ventilation having been treated in the article on WARMING AND VENTILATION, we shall confine ourselves here to a few supplementary observations. In whatever way the fresh air is supplied, there are several essential conditions to be observed, of which the following, as stated by Dr Parke, deserve special notice: (1) 'The entering air must itself be pure. It must be warmed if too cold, and cooled if too warm. (2) Its movement should be imperceptible, otherwise it will cause the sensation of draught, and will chill. The rate at which the movement becomes imperceptible is $1\frac{1}{4}$ feet per second, or 1.36 miles per hour; 2 and $2\frac{1}{4}$ feet per second, or 1.4 and 1.7 miles per hour, are imperceptible to some persons; 3 feet per second, or 2 miles per hour, is perceptible to most; $3\frac{1}{4}$ feet is perceived by all persons. Any greater speed than this will give the sensation of draught, especially if the entering air be of a different temperature, or moist. (3) It must be well diffused all through the room, so that in every part a movement shall be going on—in other words, the distribution must be perfect. (4) The *outgoing air* must be removed so immediately that there shall be no risk of a person breathing again either his own expired air or that of any other person.'—*Op. cit.* p. 103. The action of the wind is a powerful ventilating agent. If it can pass freely through a room with open doors and windows, it changes the air to an extent that can be effected in no other way. The most serious objection to winds as ventilating agents by perfation is the uncertainty of their movement, and the difficulty of its regulation. When the velocity reaches 4 miles, it is found unpleasant by most people, and is therefore either excluded, or only admitted through small openings, when it fails to become properly distributed. For the various ways in which the perflative power of the wind has been employed in systems of ventilation, we must refer to Ritchie's *Treatise on Ventilation*, 1862; Tomlinson's *Treatise on Warming and Ventilation*; and to the chapter on that subject by Dr Parke, who gives a diagram illustrating the mode in which Dr Arnott has most successfully ventilated the Field Lane Ragged Schools. In the ventilation of ships, the wind is always used, the air being directed between decks and into the hold by means of wind-sails or tubes with cowls turning towards the wind. A description of Dr Edmond's plan of ventilation, which is now commonly used in emigrant-ships, and is being adopted in the royal navy, is given in a recent article in *The Lancet*, on 'The Medical Aspects of the Abyssinian Expedition.' 'In all cases,' says Dr Parke, 'in which the air of a room—as in a basement story or in the hold of a ship, perhaps—is likely to be colder than the external air, and where artificial means of

ventilation cannot be employed, the wind should be taken advantage of as motive agent.' In artificial ventilation by a fan or screw, it is a question which of the two methods should be employed—the method of *extraction*, in which the air is drawn out of a building or room; or the method of *propulsion*, in which air is driven in, so as to force out the air already in the room. Both plans have advocates of authority. The advantages of the method of propulsion are its certainty and the ease with which the amount may be altered. The stream of air can be taken from any direction, and can be washed, cooled, or warmed at pleasure. The fan or wheel commonly used in propulsion is essentially that proposed by Desaguliers in 1734; it is figured in article BLOWING-MACHINES (figs. 7, 8) in SUPPLEMENT. The following is the way in which it is applied to one of the largest rooms in this country—St George's Hall, at Liverpool. The air is taken from the basement; is washed, by being drawn through a thin film of water, thrown up by a fountain; is passed (in cold weather) into vessels for the purpose of warming it, in which it can be moistened by a steam-jet, if the difference of the dry and wet bulb be more than five degrees, and is then propelled along the channels which distribute it to the hall. In summer, it is cooled in the conduits by the evaporation of water. This system is employed with success in various hospitals, asylums, &c. in France and America; and during the Crimean war, Mr Brunel introduced into the hospital of Renkioi a wheel of Desaguliers' at the entrance of each ward of 50 beds, which was worked by hand, and could throw 1000 cubic feet of air into the ward every minute.

For information regarding the best means of keeping the air of rooms at the most fitting temperature, we must refer to the article WARMING. The degree of artificial warmth that should be given to the air varies according to circumstances. Healthy adults, who are well fed and clothed, usually find any temperature from 50° to 60° comfortable; while children and aged persons require a temperature of 65° to 70°. In hospitals, the proper temperature is usually supposed to be about 60°; but in those diseases in which there is preternatural heat, except possibly in scarlatina, a lower temperature—as from 50° to 45°, or even 40°—is more expedient. In most febrile cases, in the acute stage, cold air moving over the body is very efficacious as a cooling agent.

The next sanitary element to be considered is WATER. The *daily quantity* of water for healthy and sick persons is the first point for consideration. Water is required by healthy persons (1) *For drinking*. A man weighing 10 stone will take on an average from 70 to 90 ounces of water in 24 hours, of which 30 or 40 ounces are taken imperceptibly in the solid food, while the remaining 50 or 60 ounces are taken in a liquid form. But the amount varies extremely. The usual allowance on board ship for both drinking and cooking is 8 pints per adult daily. (2) *For cleansing the person, clothes, and habitations*. Dr Parke estimates 4 gallons per head daily as the smallest amount; and if perfect cleanliness is to be secured, and baths* are taken, at least 16 gallons per head are required. (3) *For sewage*, an additional 9 gallons must be added. The amount for a water-closet varies with its construction. At Netley Hospital, to which Dr Parke is physician, Jennings's closets are used, which require 10 gallons per head daily.

It may be of importance to many of our readers

* A general bath requires about 50 gallons; a shower-bath at least 6 gallons; and a hip-bath from 12 to 18 gallons.

to know that a horse drinks from 8 to 12 gallons daily, and ought to have 3 or 4 more for grooming purposes; a cow or small ox drinks from 6 to 8 gallons; and a sheep or pig, from 2 quarts to 1 gallon.

The different sources of water—rain-water, rivers, and springs; the chief impurities in these waters; the methods of detecting them; and the modes of purifying bad water, are so fully described in the article WATER-SUPPLY, that we have scarcely anything to add on these points. The organic matters in different waters used for drinking purposes require, however, a few additional remarks, on account of their extreme importance in a hygienic point of view. To the remarks on this subject in pp. 100—101 of vol. ix., we may add that their amount varies from 0·3 per gallon to as much as 12 or even 30 grains per gallon, the purest waters in this respect being those from granitic, or clay-slate, or chalk districts. The most common organic matter is derived from the vegetable kingdom, and consists of humin and ulmin, and of acids derived from humus; all which substances are non-nitrogenous, although the acids combine readily with ammonia. This form of organic matter is far less dangerous than that which has an animal origin, and contains nitrogen. This organic matter is usually derived from the contents of cesspools or sewers percolating into springs. Its exact composition is not known. Fæcal and biliary matters doubtless contribute to the composition of this matter; and in addition, decomposed flesh, as the refuse of butchers' shops and slaughter-houses—substances from tripe-manufactories and gut-spinners, from size, horn, and isinglass manufactories, &c., often contribute to the organic matter of well and spring water. See Parkes, *op. cit.*, p. 12. Most of these substances, in decomposing, produce both nitrous and nitric acid and ammonia; and the nitrites and nitrates thus formed unfortunately not only do not communicate any bad taste or smell to the water, but actually tend in many cases to render it especially palatable. The use of water of this kind is liable to produce diarrhoea and choleraic symptoms.

The characters of good drinking-water—as laid down after much discussion by various sanitary congresses—are summed up by Dr Parkes as follows: 'It must be transparent, colourless, without odour, and tasteless; it should be well aerated (as it then appears to be more easily absorbed), cool, and pleasant to drink; it must have no deposit; vegetables should be readily cooked in it; the total dissolved constituents must be within a certain amount, which, with some limitation, may be represented by the following numbers: organic matter should not exceed 1·5 grains per gallon; carbonate of lime, 16 grains; sulphate of lime, 3 grains; carbonate and sulphate of magnesia, 3 grains; chloride of sodium, 10 grains; carbonate of soda, 20 grains; sulphate of soda, 6 grains; and iron, 0·5 of a grain.'

For details regarding the mode of examining water with the view of ascertaining its value for drinking purposes, we must refer to any of the leading works on Practical and Analytical Chemistry, and an especial reference may be made to Professor Miller's recent Memoir on Potable Water, and to Dr Parkes's section on the examination of water. To the substances named in the article on WATER-SUPPLY, as purifying water from organic matter, we may add the following: (1) *Potassium permanganate* of potash, commonly known as Condy's Fluid, which decomposes organic matter and ammoniacal compounds by rapid oxidation. A physician who has had long experience on board Australian emigrant-ships informs us that he has often added a small quantity to the water which, when drawn from the casks,

was almost undrinkable, with the effect of at once rendering it totally inoffensive. (On this subject, Condy's *Air and Water, their Impurities and Purification*, may be read with advantage.) (2) *Strychnos potatorum*, which is used in India to purify water; the nut being rubbed on the inside of the casks. (3) Certain vegetables containing tannin, as tea,* kino, the Laurier rose (in Barbary), and bitter almonds (in Egypt).

The consequences of an insufficient and impure supply of water are deserving of the most serious consideration. The Reports of the Health of Towns Commission (1844 and 1845) contain much information on the first of the subjects; while the Reports of the Medical Officer of the Privy Council abound in facts relating to the second subject. We find that an insufficient supply leads to the person and clothes not being washed at all, or being repeatedly washed in the same water; to water for cooking being repeatedly used; to imperfect cleansing of houses and streets; to the sewers becoming clogged, and the air thus rendered impure. The natural result is—as in the case of a deficiency of pure air—a depressed condition of the general health, with a tendency to skin-diseases, ophthalmia, &c.; while the imperfect cleansing of the sewers favours the spread of typhoid fever and of choleraic diarrhoea. We are indebted more perhaps to Mr Simon's valuable Reports than to any other source for the knowledge that a continually increasing class of cases is found to be connected with the use of impure water, the principal noxious ingredients being animal organic matter, especially when of fæcal origin; vegetable organic matters, when derived from marshes; and some salts, except when in very small quantities, as sulphates of lime and magnesia, chlorides of calcium and magnesium, nitrates and nitrites of ammonia, &c. The *alimentary mucous membrane* is especially liable, he supposes, to be affected by impure water. Thus, dyspepsia, with such symptoms as partial loss of appetite, uneasiness or pain in the pit of the stomach, nausea and constipation, with occasional diarrhoea, may be caused by water containing certain quantities (probably about eight grains each per gallon) of sulphate of lime, chloride of calcium, and the magnesian salts. *Diarrhoea* may be caused by the use of many of the great North American rivers, the Ganges, &c., where much clay is held in suspension. Water contaminated with sewage, and containing suspended animal and especially fæcal matter, is a common cause of an outbreak of this affection, and even of choleraic symptoms. Dissolved animal organic matters doubtless have a similar effect, but it is difficult to distinguish between the actions of these and of suspended organic matters. Amongst other impurities known to occasion diarrhoea are fetid gases (sulphuretted hydrogen), an excess of dissolved mineral matters and nitrate of lime; and on most persons, brackish water acts similarly. The effects which the selenitic well-waters of Paris exert on strangers are well known. There is abundant evidence to shew that impure water is one of the principal causes of *Dysentery*. The records of our army surgeons abound in illustrative cases. The deleterious effect of the impure water of Calcutta in inducing dysentery has been forcibly pointed out by Dr Chevers in the *Indian Annals* for 1864.

* The water of the Peiho and other rivers in the north of China is so impure, and has so offensive a smell during winter, that the Chinese never drink it except as tea, when it seems to lose all its bad effects. It is only by using their 'brick-tea' to purify the water of the steppes, that the Tartars render the water drinkable.

In addition to the diseases affecting the alimentary mucous membrane of the intestines, there are certain *specific diseases* which result from the use of impure water, as *Malarious Fevers* of various forms, from the use of the water of marshes; *Typhoid Fever*, from water contaminated with sewage matters, or the special typhoid poison; *Cholera*, from water into which cholera-*evacuans* have made their way; and possibly *Yellow Fever*. (The relation of impure water to typhoid fever and cholera will be more fully noticed in a later part of this article.) To the use of water unfit for drinking purposes are also ascribed epidemic boils from the presence of sulphuretted hydrogen; disease of the bones, as *exostosis*, from an excess of carbonate and sulphate of lime; *calculi* (on, we think, insufficient evidence); *goitre*, from water derived from limestone and magnesian rocks; and *entozoa* of various kinds. Dr Parkes sums up the department of his *Manual* which treats of water in a hygienic point of view with the following practical conclusions: '(1) An endemic of diarrhoea in a community is almost always owing either to impure air, impure water, or bad food. If it affects a number of persons suddenly, it is probably owing to one of the two last causes; and if it extends over many families, almost certainly to water. (2) Diarrhoea or dysentery constantly affecting a community, or returning periodically at certain times of the year, is far more likely to be produced by bad water than by any other cause. (3) A very sudden and localised outbreak of either typhoid fever or cholera is almost certainly owing to the introduction of the poison by water; and the same fact holds good in cases of malarious fever. (4) The presence of *lumbri*, guinea-worm, or *Bothriocephalus latus*, should always excite suspicion of the drinking and bathing water.'—*Op. cit.*, p. 63.

After the two most important factors in relation to health, viz., air and water, SOIL and CLIMATE occupy a secondary, although by no means unimportant place. As their practical bearing is less direct and universal, we will dismiss them briefly. Soil may affect health (1) by its conformation and elevation. Thus, amongst hills, the unhealthy spots are enclosed valleys, where the air must stagnate, and ravines. On plains, the most dangerous spots are at the foot of hills which store up water, unless a ravine cuts off the drainage. (2) Vegetation exerts an important influence. If we regard vegetation as divisible into herbage, brushwood, and trees, it may be laid down as a general rule, that herbage is always healthy, and in the tropics, is of great importance in cooling the ground, both by obstructing the sun's rays and by aiding evaporation; that brushwood is almost always bad, but that its removal may cause a temporary increase of malarious disease, on account of the disturbance of the soil; and that trees should seldom be removed, unless they decidedly interfere with the movement of the air, for in cold countries they shelter from cold winds—in hot, they cool the ground—and in both they may afford protection from malarious currents. The present condition of St Thomas in the West Indies, which is now one of the most pestilent sites we are acquainted with, is mainly due to the insane destruction of its trees. The island of Mauritius, which has lately been visited by one of the most universal and destructive forms of fever ever recorded, has similarly suffered from the same cause. (3) The mechanical structure of the soil is of hygienic importance in various points of view. Thus, heat is very differently absorbed by different soils under the same conditions of exposure. Assuming that sand with a little lime has the maximum power of retaining

heat, and that its capacity be represented by 100, then the capacity of clay will range from 76.9 to 66.7; while that of chalk will be 61.8, and that of humus as low as 49. Hence, we see the comparative coldness of the latter soils as compared with sand. The capacities of these soils for absorbing and retaining moisture are in the reverse order.

As a general rule, there seems to be the following connection between the geological characters of a site and its probable healthiness. *Granitic, Metamorphic, and Trap Rocks* are usually healthy: there is generally a slope, so that water runs off readily, the air is dry, vegetation moderate, and drinking-water generally good. They are, however, supposed to be unhealthy when they have become disintegrated, as at Hong-kong, into a dark-coloured soil. *Clay-slate Rocks* are regarded as healthy, for very similar reasons; water, however, is often scarce. Of the varieties of *Limestone Rocks*, the hard oolite is the best, and the magnesian (which, if possible, should always be rejected as a site) the worst. *Chalk*, when unmixed with clay, forms a very healthy soil; but if it be mixed with clay, it loses its permeability, and is often damp and cold. The air is pure, and the water, though hard, is clear, sparkling, and pleasant. The *Sandstones*, if permeable, are healthy; but if, from an admixture or underlying of clay, they lose this property, they are often damp. The water must be carefully examined. The hard millstone grits are very healthy. *Gravels* of any depth are healthy, except water rises through them. Dr Parkes considers gravel-hillocks as the healthiest of all sites, and the water as being very pure. *Clay, Dense Marls, and Alluvial Soils* must be regarded with suspicion. Such soils, and especially the deltas of rivers, should, if possible, be avoided as sites, and if they must be chosen, thorough sub-soil draining, careful purification of the water, and elevation of the houses far above the soil, are the measures to be adopted. According to Dr Forbes Watson, nearly one-third of the whole surface of India is covered by alluvial soil.

CLIMATE.—The most important climatic conditions connected with the air are *temperature, humidity, and movement, weight, and composition of the air*. Under the head of temperature we might enter into the general subject of acclimation; we must, however, confine ourselves to the remark, that Europeans from temperate climates seem to flourish in countries not much hotter than their own, as in some parts of Australia and New Zealand, although it is yet too soon to decide whether the general vigour of the race will improve or diminish. In countries with a yearly mean of 20° F. higher than their home climate, as in many parts of India, the race seems to dwindle, and gives indications of dying out. The endemic diseases of Europeans in the tropics are liver-disease and dysentery, but it is uncertain how far other influences may be at work besides heat in the production of these diseases. Rapid changes of temperature are always dangerous. The sudden check to the free action of the skin caused by a cold wind, is sure to give rise to catarrh, inflammations, and neuralgia. The Registrar-general's returns shew that when the temperature in London falls from 45° to 27°, the weekly mortality is increased by 400, bronchitis being the disease which mainly causes this increase—an affection which usually does not prove fatal in more than about 40 cases weekly. The fatal influence of extreme cold in depressing the nervous system, and giving rise to a sleep from which there is no awakening, is noticed in the article COLD. According to their humidity, climates are also divided into *moist* and *dry*. The most agreeable

amount of moisture to most persons is when the relative humidity* is between 70 and 80 per cent. In chronic lung-diseases, a still moister air is most pleasant, and serves to allay cough. The morbid effects of undue moisture are always associated with rise of temperature. As a general rule, warmth and great humidity are less oppressive than cold and great humidity. There seems to be close relation between the spreading and the checking of certain epidemic diseases and the relative moisture of the atmosphere. The malarious diseases are most intense when the moisture is excessive; while plague and small-pox are checked by a very dry atmosphere. Yellow fever seems unaffected by this atmospheric condition. That the humidity of a climate, irrespective of other climatic relations, is not injurious to life, may be inferred from a comparison between the climates of England and Ireland. The number of persons over 100 years of age is, in proportion to the population, five times as great in Ireland as in England, and the greatest longevity has been observed in Connaught, the wettest of the provinces.† See Mapother, *op. cit.*, p. 134.

The movement of the air is another climatic condition of importance, but it must be considered in connection with heat and moisture. A cold wind abstracts the bodily heat in proportion to its velocity; while a hot wind, if dry, increases evaporation, and may thus partly neutralise its own heating power. Variations in atmospheric pressure are of great importance in relation to health. 'In ascending mountains,' says Dr Parkes, 'there is rarefaction, i. e., lessened pressure of air, lowered temperature, and lessened moisture above 4000 feet; greater movement of the air; increased amount of light; greater sun-radiation, if clouds are absent; and the air is freer from germs of infusoria. Owing to the rarefaction of the air and watery vapour, there is greater diathermancy of the air; the soil is rapidly heated, but radiates also fast, hence very great coolness of the ground and of the air close to it at night.'—*Op. cit.*, p. 418. The physiological effects of lessened pressure begin to be perceptible at somewhat less than 3000 feet, at which altitude the mercury falls 3 inches. The pulse is quickened by 15 or 20 beats, and the breathing by 10 or 15 inspirations per minute; there is increased evaporation from the skin and lungs, while the urinary secretion is probably diminished. At an elevation of 6000 or 7000 feet, as in the Swiss Alps, the effect of the mountain air shews itself in a marked improvement in digestion, sanguification, and in nervous and muscular vigour. At great heights, there is swelling of the superficial vessels, and occasional bleeding of the nose and lungs; and a sensation of weight is felt in the limbs from the lessened pressure on the joints. A residence for some time in a mountain-air is of great value in all anæmic affections, from whatever cause they may arise. Neuralgia, gout, and rheumatism are all benefited by high alpine positions (see Weber *On the Climate of the Swiss Alps*, 1864); and scrofula, and consumption are almost absent in the true alpine regions, while patients affected with these diseases, if brought to such a climate, rapidly improve. On the other hand, pneumonia, pleurisy, and acute bronchitis are more common in high regions than lower down. The

* By relative humidity we express comparative moisture, complete saturation being assumed to be 100. It is determined by dividing the weight of vapour actually existing in the air (or the absolute humidity), by the weight of vapour which would have been present if the air had been saturated.

† The average annual relative humidity of Ireland is 88, but on many days it attains as high a point as 94.

disease formerly known as 'mountain asthma' seems, from Weber's observations, to be common pulmonary emphysema combined with or followed by chronic bronchitis.

FOOD is a subject which has been already considered in the articles DIET and FOOD AND DRINK. There are, however, certain points connected with it which obviously fall within the domain of hygiene; as, for example, (1) the quantity of the different kinds of food required for persons of different sexes and ages, and under varying conditions of life and climate; (2) the determination of the best articles of food in each class, and whether they are in a proper state for use. The first of these subjects is to a considerable degree discussed in the article DIET. The latest and probably the most accurate statements on this subject are those of Pettenkofer and Voit (quoted in Parkes's *Sanitary Report of the Army for 1865*); a strong average man requires, according to these physiologists, 5.22 oz. of dry nitrogenous matters, 3.63 oz. of fat, and 13.3 oz. of carbohydrates. They also find that when the food is sufficient, the daily excretion of carbon from the lungs is 8.92 oz. or 3902 grains. We may add that an average man, at moderate work, takes, in 24 hours, from $\frac{1}{4}$ th to $\frac{1}{3}$ th of his own weight in solid and liquid food—viz., from 34 to 46 ounces of so-called solids, as bread, meat, &c.; and from 50 to 80 ounces of water. The ratio of the solid to the liquid food is generally 1 to 2, but may be 1 to 6. Great bodily exercise requires a greater increase of the solid than of the liquid food.

It may be interesting to many readers to know the amount and nature of the daily diet of an English soldier* on home service and the railway navy:

| Soldier. | | Navy. | |
|-----------------------------|------|-----------------------------|------|
| | Oz. | | Oz. |
| Meat, | 12 | Meat, | 13.7 |
| Bread, | 24 | Bread, | 28.5 |
| Potatoes, | 16 | Potatoes, | 7 |
| Other vegetables, | 8 | Other vegetables, | 0.57 |
| Coffee, | 0.33 | Butter, | 0.57 |
| Tea, | 0.16 | Cheese, | 1.7 |
| Salt, | 0.26 | Beer, | 37 |
| Sugar, | 1.33 | Coffee, | 0.5 |
| Milk, | 3.25 | Cocoa, | 1.1 |

Deputy-inspector-generals O'Flaherty and Taylor, and Assistant-surgeon Spurway, have just published (1867) important articles on the diet of soldiers in the 7th volume of the *Statistical, Sanitary, and Medical Reports for the year 1865*, from which it would appear that, *inter alia*, an addition to the fatty food would be expedient. For information on the *Dietary of Workhouses and Prisons*, we must refer to Dr E. Smith's admirable report on the former subject, and to Dr Lankester's paper, 'On Prison and Workhouse Diets,' read before the Health Department of the Social Science Congress at Belfast—an abstract of which may be found in the *British Medical Journal* for November 2, 1867. The whole subject of prison dietaries requires revision. While in some favoured institutions the prisoners live in comparative luxury, in others the dietary scale is far too scanty. The Irish prisons are especially faulty in this respect; the daily expense of the food per head seldom reaching fourpence, and in some jails being only *twopence*! At Waterford jail no food is allowed from 3 P.M. to 8 A.M., and in the Irish jails generally a pint of skim milk constitutes the whole animal diet. It is understood that a commission has been issued to report

* We learn from Froude's *History of England*, that in the reign of Edward VI. the English soldier's rations during war were, meat, 2 lbs.; bread, 1 lb.; light French wine, 1 pint.

upon this subject. The proper arrangement of diet for the sick is a matter of great difficulty. In hospitals, fixed scales must, as a matter of convenience, be adopted; but almost every special case requires a modification. For further information on special diets, the reader is referred to Moleschott's *Physiologie der Nahrungsmittel* (1860); to Dr Dobell's useful *Manual of Diet and Regimen*; and to Dr Smith's *Practical Dietary for Families, Schools, and the Labouring Classes*.

The diseases connected with food are so various that we can only notice the most important. Passing over those which arise from excess of food generally, or of one of its classes, with the remark, that a prolonged excess of albuminates gives rise to congestion and enlargement of the liver, and a general state of plethora, while excess of starchy matters may possibly affect the muscular fibres of the heart and voluntary muscles, and certainly often renders the urine saccharine, we proceed to notice the diseases produced by the deficiency of food. The history of epidemic fevers in all ages and countries shews the close relation between famine and fever. The *Irish famine* of 1847—1849 is now a matter of history. In those three years, no less than 579,721 cases were treated in the hospitals alone. Fleeing in despair, emigrants carried the germs of disease with them; and the so-called *ship-fever* which followed destroyed its thousands. Its malignity was most appalling. In one vessel, 329 out of 349 passengers caught the fever, and 117 died; and the mortality in Liverpool, induced by the contagion of the fever-stricken Irish who landed there, suddenly became the highest ever recorded in any modern town—the death-rate being raised to 70 per 1000. During the last three years, 1865—1867, the death-rate of this town was 36, 42, and 30. Dr Mapother is of opinion that the introduction of the potato as an almost sole article of diet has been productive of much harm, in consequence of the deficiency of that root in nitrogenous matters and in salts of lime and magnesia.* To this source he traces indigestion, consumption, scrofula, rickets, ophthalmia, and chronic rheumatism. The deprivation of starchy food, on the other hand, can be borne for a long time if fat be given; but the simultaneous deprivation of fat and starch soon induces illness, though albuminates be supplied.

With regard to salt meat, it must be recollected that the brine, if it has been used several times, occasionally becomes poisonous. The evidence as to the power of diseased meat when eaten to excite disease, is—if we except the cases in which entozoa are present—very unsatisfactory. We have the evidence of Sir Samuel Baker and others that certain African tribes eat without injury meat swarming with maggots. In this country, the flesh of healthy animals, when decomposing, is sometimes eaten with impunity, and sometimes occasions severe gastric

* Potatoes contain 74 per cent. of water, 1.5 of albuminates, 0.1 of fat, 23.4 of starch, cellulose, &c. (the carbohydrates), and 1 of salts. The chief ingredients of the salts are potash, about 50 per cent.; and phosphoric acid, about 13 per cent. The juice of the potato abounds in salts of organic acids (citric, tartaric, &c.), which on incineration are converted into carbonates—the carbonic acid thus formed amounting to 13.3 per cent. The relative proportion of fat to albuminates in the food which is most easily digested, and at the same time produces the greatest mechanical force, is as 1 to 2; in the potato, it is as 0.1 to 1.5, or as 1 to 15. Again, the starchy matters should be to the nitrogenous as 3 to 1 in the best diet: in the potato, they are as 23.4 to 1.5, or as 14 to 1 nearly. On this subject see the article **MUSCULAR FORCE, ORIGIN OF, IN SUPPLEMENT.**

intestinal disorders. There is reason, however, to believe that if slightly tainted meat, poultry, or river fish be washed in a very dilute solution of Condy's fluid, previous to being cooked, all danger is removed. The occasional occurrence of a poison in sausages and even in pork pies is well known, although its nature is not clearly understood. The fresh flesh of diseased animals assuredly causes injurious effects in many cases, but not in all. In the early stage of acute inflammatory disease, the meat is not altered, and may be eaten with impunity. Whether the epidemic pleuropneumonia of cattle renders their flesh unfit for use, is an open question. (See Mapother, *op. cit.*, pp. 217—224, who decidedly condemns its use, and Parkes, *op. cit.*, pp. 161—166, who quotes conflicting evidence.) The discrepancy of evidence is equally great regarding anthrax and malignant pustule. The death of sheep from splenic apoplexy or braxy, and from small-pox, renders their flesh unfit for food; while the flesh of cattle destroyed by foot-and-mouth disease and by typhoid fever has been largely used in France without injury. The detection of the adulterations of the ordinary articles of food is a very important duty in relation to hygiene; on this subject, we must refer to Hassall's great work, and to our article **FOOD**.

The object of **CLOTHING** is to preserve the proper heat of the body by protecting it both from cold and heat, and thus to prevent the injurious action of sudden changes of temperature upon the skin. The most important materials of clothing are cotton, linen, wool, silk, leather, and india-rubber. *Cotton*, as a material of dress, wears well, does not readily absorb water, and conducts heat much less rapidly than linen, but much more rapidly than wool. From the hardness of its fibres, its surface is slightly rough, and occasionally irritates a very delicate skin. Its main advantages are cheapness and durability. In merino it is mixed with wool in various proportions, and this admixture is far preferable to unmixed cotton. *Linens* is finer in its fibres than cotton, and hence is smoother. It possesses high conducting and bad radiating powers, so that it feels cold to the skin; moreover, it attracts moisture much more than cotton. For these reasons, cottons and thin woollens are much preferred to linen garments in warm climates. *Silk* forms an excellent underclothing, but from its expense, it can never come into general use. *Wool* is superior both to cotton and linen in being a bad conductor of heat, and a great absorber of water, which penetrates into the fibres and distends them (hygroscopic water), and also lies between them (water of interposition). 'This property of hygroscopically absorbing water is,' as Dr Parkes observes, 'a most important one. During perspiration, the evaporation from the surface of the body is necessary to reduce the heat which is generated by exercise. When the exercise is finished, the evaporation still goes on, and to such an extent as to chill the frame. When dry woollen clothing is put on after exertion, the vapour from the surface of the body is condensed on the wool, and gives out again the large amount of heat which had become latent when the water was vaporised. Therefore, a woollen covering, from this cause alone, at once feels warm when used during sweating. In the case of cotton and linen, the perspiration passes through them, and evaporates from the external surface without condensation; the loss of heat then continues. These facts make it plain why dry woollen clothes are so useful after exertion. In addition to this, the texture of wool is warmer, from its bad conducting power, and it is less easily penetrated by cold winds.'—*Op. cit.*, p. 353. *Leather*

is used not only for shoes, boots, and leggings, but, in cold windy countries, for coats. Leather and sheep-skin coats are in common use in Turkey, Tartary, Persia, the Danubian Provinces, and in Canada, where buffalo-skins are often used. For persons specially susceptible to cold, and of delicate organisation, a chamois leather jacket worn over a flannel waistcoat may be recommended with advantage during the winter months. *India-rubber* clothing must be used with extreme caution. From its being impenetrable to wind, and from its condensing and retaining the perspiration, it is decidedly objectionable; while, on the other hand, its protection against rain is a very valuable property. The Council of Health of the French army have refused to admit waterproof garments amongst their soldiers; and in this country it has been prohibited amongst the London postmen.

In relation to protection against heat, we have to consider the colour and not the texture of clothing. White is the best colour, then gray, yellow, pink, blue, and black. Hence, in hot countries, white or light gray clothing should be preferred.

The shape and weight of all articles of clothing should be such as to allow of the freest action of the limbs, and in no way to interfere by pressure with the processes of respiration, circulation, or digestion. In a complete treatise on hygiene, a discussion on the relative advantages and disadvantages of the various articles of clothing used by both sexes would find a proper place, but our limited space totally precludes us from entering into this subject.

Attention to the STATE OF THE SKIN is of great importance in a hygienic point of view. The perspiration and sebaceous matters which are naturally poured out upon the surface of the body, with an intermingling of particles of detached epidermis, fragments of fibres from the dress, dirt, &c., if not removed, gradually form a crust which soon materially interferes with the due excreting action of the skin. There is little doubt that the daily use of the matutinal tub, which less than half a century ago was unheard of, and is now a matter of necessity with most healthy persons who have the means of using it, has contributed materially to harden the system against attacks of colds, rheumatism, &c. When a tub and sponge happen to be unattainable, a wet towel rubbed over the body, followed of course by a dry one, is a good substitute.

EXERCISE is the subject that next claims our consideration, and we shall briefly notice its effects on the different systems of organs. (1) The most important effect of muscular exercise is produced on the *lungs*, the quantities of inspired air and of exhaled carbonic acid being very much increased. Taking the air inspired in a given time in the horizontal position as unity, a man walking 3 miles per hour inspires 3.22; and if carrying 34 lbs., 3.5; a man walking 4 miles per hour inspires 5; and when walking 6 miles per hour, no less than 7. Almost twice as much carbonic acid is exhaled during exercise as during rest. Hence, muscular exercise is necessary for the due removal of the carbon; and it is obvious that in a state of prolonged rest, the carbonaceous food must be diminished, or the carbon will be liable to accumulate in the system; and further, it is clear that, for strong exercise, carbonaceous food should be freely given. (2) The action of the *heart* rapidly increases in force and frequency during exercise. The increase in the number of beats may range from 20 to 30, and is sometimes much more. After exercise, the heart's action is diminished. Excessive exertion

may do harm by inducing pulmonary congestion, and even hæmoptysis, palpitation, hypertrophy, valvular disease, and occasionally rupture; while deficient exercise probably tends to induce tuberculous disease of the lung, weakness of the heart's action, and probably dilatation and fatty degeneration. From these facts we learn, that when a person commences any new form of exercise or gymnastics, the heart's action should be watched, and if the pulse rise to 120 or more, the exercise should for the time cease. (3) The *skin* becomes red from increase of blood in the capillaries, and the perspiration is increased, being at least doubled. The bodily heat is kept down by cutaneous evaporation, which reduces the temperature. During exertion, there is very little danger of chill, but the danger becomes great when the exertion is over, because there is then a rapid fall in the heat of the body, while the evaporation of the skin continues. Hence, while the skin may be freely exposed during exercise, it must be covered immediately afterwards, in order to prevent any feeling of coolness on the surface. (4) The *muscles* grow to a certain limit, but over-exercise of any special group may produce wasting. Care must be taken that the exercise is of such a nature that all the muscles, and not single groups, should be brought into play; and that in early training, long intervals of rest should intervene between the periods of exercise. (5) The effect of exercise on the *mind* is not clearly determined; great bodily activity is often observed in association with full mental activity; but there is a fear that, in our great public schools and universities, boating and cricket are supplanting more useful subjects, and leaving too little time for the due performance of intellectual work. (6) *Digestion* is improved by exercise. The appetite increases, and nitrogenous substances, fats, and salts, especially phosphates and chlorides, are required in greater quantity than in a state of rest. (7) The *change of tissues* is increased by exercise, or, in other words, the excretions give off increased quantities of carbon, nitrogen, water, and salts. The muscles require much rest for their reparation after exercise, and they then absorb and retain water, which seems to enter into their composition. So completely is the water retained in the muscles, that the urine is not increased for some hours. Hence, observes Dr Parkes, there is an absolute necessity of water for the acting muscles, and the old rule, held by trainers, of only allowing the smallest possible quantity of fluid, must be wrong.

The amount of exercise which should be taken by an adult healthy man is a subject of great importance. Professor Haughton, in his *New Theory of Muscular Action*, calculates that a labouring man daily exerts a muscular force to a degree which may be expressed by saying, that he would raise to the height of 1 foot from 250 to 350 tons. For persons not obliged to labour, the force expended, including that required for the ordinary avocations of life, should average 150 tons, which is equivalent to walking about 9 miles daily. It is unfortunately impossible to arrange scales of exercise for invalids, women, and children. Professor Haughton has shewn that walking on a level surface is equivalent to raising the $\frac{1}{4}$ th part of the weight of the body through the distance walked. When ascending a height, a man of course raises his whole weight through the height ascended. Using his formula, $W + \frac{WD}{20 \times 2240}$ (where W is the weight of the person, W' the weight carried, D the distance walked, 20 the coefficient of traction (see FRICTION), and 2240 the number of pounds in a ton), we obtain as a

for a new tenant varies with the soil and the distance of the body from the surface. Under favourable circumstances, a coffin containing an adult will disappear with its contents in about 10 years; while in a clayey or peaty soil, it will remain a century. It is generally assumed that a period of 14 years is sufficient for the decay of an adult, but long before this time, all will have disappeared but the skeleton. If the question should in course of time arise between burying in the sea and burning, it will be decided, Dr Parkes believes, in favour of the former, on the following grounds: 'It is true that the impurities in burning can be well diffused into the atmosphere at large, and would not add to it any perceptible impurity. But if the burning is not complete, fetid organic matters are given off, which hang cloud-like in the air, and may be perceptible and even hurtful. As a matter of expense, too, the system of incineration would be greater than the burial at sea. In the burial at sea, the body would go at once to support other forms of life more rapidly than in the case of land-burial, and without the danger of evolution of hurtful products.' On this subject, the reader may further consult the Report drawn up by Mr Chadwick on the State of Cemeteries; the Report of the General Board of Health, 1858 (of which Mr Chadwick and Dr Southwood Smith were members), on the same subject; Dr Mapother's 14th Lecture 'On the Burial of the Dead;' and a work just published by M. Favrot, entitled *Histoire des Inhumations*, 1867.

The Reports to which we have just referred contain abundant evidence of the necessity for the universal establishment of mortuaries, or houses for the reception of the dead until the period of the burial. In some parts of Germany, the deposit of the dead in such houses is compulsory; and in many parts of the continent, there are laws rigidly enforcing the burial within a certain number of hours after death.

Before proceeding to consider how far our sanitary regulations have effected a saving of human life, it is expedient to give a brief notice of the chief acts of parliament which have passed, and government Reports that have been officially published, bearing on important sanitary subjects. Beginning with 1833, in which the Factory Children's Act was passed; in 1834, the practice of employing climbing boys for sweeping chimneys was abolished; in 1840 and 1841, the Act to Extend the Practice of Vaccination was passed; and in 1842, the employment of women and children in mines and collieries was abolished. Then appeared the General Local Reports on the Sanitary Condition of the Labouring Classes, 1842, which constitute, as Dr A. P. Stewart well observes, a 'remarkable series of volumes, for which we were indebted chiefly to Mr Chadwick, and which, revealing as they did an almost incredible state of matters in our crowded centres of population, were read by multitudes with a strange and eager interest.'—*The Medical and Legal Aspects of Sanitary Reform* (1867), p. 5. These Reports of the Health of Towns Commission led to the passing, in rapid succession, of 'the Acts for Promoting the Establishment of Baths and Wash-houses in Great Britain and Ireland, in 1846; the Towns Improvement Act, in 1847; the Public Health, the Nuisances Removal, and the City of London Sewers Acts, in 1848; the Metropolitan Interments Act, in 1850, followed in 1853 by a similar act for the whole of England; the Act to Encourage the Establishment of Lodging-houses for the Labouring-classes, and the Common Lodging-houses Act, in 1851; the Metropolitan Water Act, in 1852; the Smoke Nuisance Abatement (Metropolis) Act, and the Act to Extend and

Make Compulsory the Practice of Vaccination, in 1853; the Merchant Shipping Act, with its stringent provisions for the preservation of the health of our merchant seamen, in 1854; the Diseases Prevention, the Metropolis Local Management, the Metropolitan Buildings, and the Nuisances Removal Amendment Acts, in 1855; and the Public Health Act of 1858, which abolished the General Board of Health, and vested its powers in the Privy Council. Since then, there have been added to the statute-book the Acts for the Purification of the Thames, in 1858 and 1866; the Act for Preventing the Adulteration of Articles of Food and Drink, in the same year; the Acts (passed in 1860, 1861, and 1864) which included, under the provisions of the Factory Act, women and children employed in bleaching and dyeing works, in lace factories, and in the manufacture of earthenware, of lucifer-matches, of percussion caps and cartridges, of paper-staining and of fustian-cutting; the Vaccination Amendment Act in 1861; the Act for the Seizure of Diseased and Unwholesome Meat, and the Alkali Works Act, in 1863; the Sewage Utilisation Act, in 1865; the Labouring-classes' Dwelling-houses Act, and the Sanitary Act, in 1866.—Stewart, *op. cit.*, p. 6. The last-named of these acts—the Sanitary or Public Health Act of 1866—contains certain clauses with which every one should be acquainted. Its first part is an amendment of the Sewage Utilisation Act, 1865, and provides, *inter alia*, that any owner or occupier of premises within the district of a sewer authority shall be entitled, under certain conditions, to cause his drains to empty into the sewer; but if a dwelling-house is without efficient drainage, the sewer authorities may require the owner to make a sufficient drain, emptying into a sewer, provided the latter be not more than 100 feet distant; and that the sewer authority may provide a supply of water for the use of the inhabitants of the district. The second part is an amendment of the Nuisances Removal Acts—the word 'nuisance' being made to include (1) any house or part of house so overcrowded as to be dangerous or prejudicial to the health of its inmates; (2) any factory or workshop not kept clean and properly ventilated; (3) any fireplace or furnace not, as far as possible, consuming its own smoke; and any chimney (not belonging to a private house) sending forth black smoke. The rules for the removal of such nuisances are laid down. The nuisance authority, moreover, has power to enforce the cleansing and disinfecting of houses or articles therein likely to retain infection, and to fine those who disregard the injunction; to provide a proper place for disinfecting clothing, bedding, &c., and to effect the disinfection of such articles; to provide carriages for the conveyance of infected persons to hospitals, &c. The 25th clause is so important, and its nature so very little known, that we extract it *verbatim*: 'If any person, suffering from any dangerous infectious disorder, shall enter any public conveyance without notifying to the owner or driver thereof that he is so suffering, he shall, on conviction thereof before any justice, be liable to a penalty not exceeding £5, and shall also be ordered by such justice to pay to such owner or driver all the losses and expenses they may suffer in carrying into effect the provisions of the act; and no owner or driver of any public conveyance shall be required to convey any person so suffering until they shall have been first paid a sum sufficient to cover all such losses and expenses.' The act further lays it down that places for the reception of the dead may be provided at the public expense, and that any justice may, on the certificate of a legally qualified medical practitioner, order the removal thither of the bodies

of those who die of infectious disease;* and gives permission that special places for the performance of *post-mortem* examination may be provided. The third part of the act is headed 'Miscellaneous.' It treats of various points for the better management of lodging-houses, lays a penalty not exceeding £5 on any person with infectious disorder exposing himself, or on any person in charge of such a sufferer causing such exposure; and a penalty not exceeding £20 on persons letting houses, rooms, or part of a house in which infected persons have been lodging, without having such houses, or rooms, and articles therein, disinfected to the satisfaction of a qualified medical practitioner (the keeper of an inn is deemed to let part of a house to any person admitted as a guest into such inn). It is very much to be regretted that most of the provisions of this and other acts bearing on public health are permissive, and not peremptory.

We may note that since 1858 a Public Health Department has been established in the Privy Council, and that the Medical Officer of the Privy Council, Mr Simon, has, since that date, published an annual Report of the Proceedings taken under the Public Health Act, 1858. These Reports, of which nine have now appeared, are of the highest importance; and we should not omit to mention that the progress of sanitary science has been considerably advanced by the publication of an annual volume (of which seven have now appeared) of statistical, sanitary, and medical army reports, by the establishment of the Epidemiological Society and the Social Science Congress, and by the publication of their Transactions.

It is much to be regretted that the Privy Council does not more energetically carry out the powers conferred on them by the Diseases Prevention Act, 1855, and the Public Health Act, 1858. Unfortunately, however, it requires some comparatively rare and startling disease, as yellow fever, plague, cholera, or cattle-disease, to stir that august body into activity; while typhus, typhoid, and small-pox may ravage our crowded towns and undrained villages, and carry off their thousands of victims, unless in very extreme cases, to which the public press may have called attention. (Of the half million deaths that occur annually in England, more than 20,000 are due to typhus and typhoid; † while in England and Scotland, more than 5000 persons annually fall victims to small-pox. †) By the Sanitary Act, 1866, the Home Secretary is empowered to interfere, if he see fit, on complaint made to him of the default of any local authority. It is sincerely to be hoped that he will unsparingly put forth the power intrusted to him.

Passing from what has, and what has not, been done by government, let us consider what are the duties of local authorities, and how they discharge them. On this subject, Dr Stewart gives us much information in his pamphlet already referred to. To such an extent has non-interference prevailed that, except in London, the appointment of Medical Officers of Health, and even of inspectors of nuisances, is optional. He ascertained, that of 570 places under the Local Government Act, 1858, and the Public Health Act, 1848, with populations varying from 214 to 200,000, 50 have no inspectors

of nuisances, 153 have each one; while in 347, one man holds the double or treble offices of surveyor, inspector, and collector. In the metropolitan districts, with a population of above 3,000,000, the sanitary force is most unequally divided, for, while 2 subdistricts, with a population of 4000 and 10,000 respectively, have the services of one inspector, St Marylebone and St Pancras, with respective populations of 163,000 and 211,000, have each of them only two.

A few words on the duties, qualifications, and position of the Medical Officer of Health, will find a fitting place here.* His duties and qualifications are thus laid down in an Instructional Minute of the General Board of Health, dated December 20, 1855: 'He will make himself familiar with the general features of the place, with its previous sanitary state, and with its existing provisions for health—viz, the levels, inclinations, soil, wells, and water-springs; with its meteorological peculiarities; with its burial-grounds, slaughter-houses, lodging-houses, &c.; he will see to the general healthiness of his district, inquire into the cleanly and waterproof condition of houses, examine the drinking-water, and observe whether diseased meat or adulterated articles of food are exposed for sale; and will report weekly and annually to the Local Board.' These are but a few of his duties, for the proper performance of which (as the Minute goes on to add), special qualifications in science are required. 'These lie in pathology, including vital statistics, in chemistry, and in natural philosophy.' For these accomplishments, the town of Aberdare offers 8*s*. 6*d*. a day, or 12 guineas a year, for looking after the health of its 35,000 inhabitants; while Paisley gives £20 for the sanitary superintendence of a population of 48,000. Fifty pounds is a common salary, except in the metropolis; the most liberal salaries are £350 at Birkenhead and Hackney, £400 at St Marylebone, £500 at Edinburgh and Leeds, £600 London (Proper), while Liverpool has nobly raised the salary to £1000. Surely £500, £600, and £1000 are not too much for Edinburgh, London, and Liverpool to pay, in order to secure the services of such men as Littlejohn, Letheby, and Trench. Dr Gairdner, one of the first of our living hygeists, receives only £200 as Officer of Health for Glasgow, the richest city in Scotland. Not only is the medical officer's (often beggarly) salary dependent on the caprices of the local board, who may dismiss him at pleasure, but, as Dr Stewart truly observes, 'the very efficiency with which he performs his duties may be an unpardonable sin in the eyes of a majority of his masters. His statements of facts may touch the interests of some, his suggestions of remedies may excite the displeasure of others; and if the soundness of his position cannot be assailed by reasoning, passion may suggest—as it has before now suggested—a reduction of salary or a threat of dismissal, as likely to bring the offender to his senses.' Not only is this disgraceful form of pressure brought to bear *directly* on the Medical Officer of Health, but *indirectly* on those who have the power of electing or dismissing him. An amusing incident of this nature is mentioned in Dr Stewart's pamphlet. When Dr Robinson was appointed Officer of Health for Leeds, he found that he had to grapple with unparalleled privy abominations,

* Liverpool alone, so far as we know, has as yet taken advantage of this clause. The Council have ordered the erection of two mortuaries; and a Protestant gentleman, Mr Hutcheson, is about to erect, at his own cost, a mortuary chapel for the Roman Catholics. (Stewart, *op. cit.*, p. 74.)

† According to Dr W. Budd, typhoid alone is the cause of from 15,000 to 20,000 deaths in England.

‡ For data on this subject, see the foot-note to p. 713.

* On this subject Dr Letheby has recently published an excellent Memoir, which will be found in the *Medical Press and Circular* for August 7 and 14, 1867; and Dr Rumsey's address *On State Medicine in Great Britain and Ireland* (Lond. 1867), may also be consulted with advantage.

piggeries by hundreds, numerous slaughter-houses, the gigantic smoke-nuisance, and an average death-rate of 30 in 1000. The battle between science and filth was prolonged and terrific, and the piggeries were made the battle-field. The pig-owners, taking alarm at Dr Robinson's energy, formed themselves into a 'Pig Protection Society,' summoned ward-meetings, and commenced an active canvas, for the purpose of turning out of the council all who would not pledge themselves to vote for Dr Robinson's dismissal. The case, after being twice heard before the magistrates, who declared that the pigs were a nuisance, and must be removed, was finally settled on appeal by the recorder, who gave an order, not for the eviction of the pigs, but for the daily removal of the manure, for the due enforcement of which a separate inspector would be required for every pig-sty! Under these conditions, is a Medical Officer of Health fairly encouraged to discharge his proper duties?

The next points to which we shall direct attention are the NUMBER OF DEATHS occurring annually in England and Wales, and the CAUSES OF THESE DEATHS; and we shall then proceed to inquire how far the deaths from some of our most fatal diseases might have been prevented by due attention to sanitary measures. We learn from the Twenty-eighth Annual Report of the Registrar-general of Births, Deaths, and Marriages in England, which is just published (1867), and gives the results for the year 1865, the following statistical facts, which bear more or less closely on our subject. The population of England, the births, deaths, and excess of births over deaths, are tabulated from the year 1838, when the system of registration came in force; and from this table we extract the numbers for 1838, 1848, 1858, and for 1861—1865 inclusive:

| Years ending Dec. 31. | Estimated Population in middle of year. | Births (exclusive of still-born). | Deaths. | Excess of Births. |
|-----------------------|---|-----------------------------------|---------|-------------------|
| 1838, . | 15,312,266 | 463,787 | 342,760 | 121,027 |
| 1848, . | 17,340,492 | 563,059 | 360,833 | 163,226 |
| 1858, . | 19,471,891 | 655,481 | 449,666 | 205,825 |
| 1861, . | 20,119,314 | 696,406 | 435,114 | 261,292 |
| 1862, . | 20,336,417 | 712,684 | 436,668 | 276,118 |
| 1863, . | 20,564,137 | 737,417 | 473,537 | 263,880 |
| 1864, . | 20,778,308 | 740,375 | 485,431 | 244,744 |
| 1865, . | 20,980,946 | 748,069 | 490,909 | 257,160 |

From these figures, we learn, *inter alia*, that in a quarter of a century the population has added 5,000,000 to its strength, and that there is a steady increase (with occasional exceptions) in the annual number of births and deaths, and in the excess of the former; the number of births having increased during that period 46 per cent., and that of deaths 43 per cent. The following is an abstract of Dr Farr's letter to the Registrar-general on the causes of death in England in 1865: In every 1000 deaths, 381 of the population fell before local diseases, 235 were struck down by zymotic diseases, 182 by constitutional diseases, 160 by developmental diseases, and 36 died violent deaths; the remaining 6 were deaths from causes not ascertained. *Local diseases*—the inflammations and functional diseases of organs—carried off 184,877 persons in England, causing 9 of the 23 deaths per 1000 of the living. It is the deaths from diseases of the vital organs that swell this number so high—22,272 deaths from heart diseases, nearly as many (21,774) from diseases of the digestive organs, more than thrice as many (69,952) from diseases of the respiratory organs so essential to life, and a number nearly as large as this last (60,264) from diseases of the nervous system. The number of deaths in England ascribed to bronchitis has rapidly increased; it was but 21,628 in

1856, had advanced to 32,346 in 1860, and in 1865 reached 36,428. Softening of the brain is another disease that has increased rapidly of late years, and in 1865 was fatal to 1051 males and 627 females: these deaths would formerly have been classed under paralysis and other heads. The deaths from diseases of the nervous system include 26,722 from convulsions, occurring chiefly in children. Among the rarer deaths from local diseases, 5 are referred to fright, 3 to grief, and 43 to melancholy. The second most fatal class of diseases—the *zymotic* (epidemic and contagious)—is swelled chiefly by fevers and by diarrhoeal disease. It swept from life in England 113,948 persons in 1865, the majority of them young children under 5 years of age. The deaths by cholera in England in 1865 were 1291; by diarrhoea, 23,531. The deaths by fever—typhus, typhoid, and typhina*—which were 13,012 in the year 1860, rose to 23,034 in 1865, and five-tenths of them were registered among four-tenths of the population. The deaths from scarlatina were 17,700, and from diphtheria, 4145. The deaths attributed to syphilis rose to 1647; 437 persons died from intemperance, and 612 from *delirium tremens*; 74 from privation; 19 from hydrophobia; 4 from glanders, for horses as well as dogs communicate some of their diseases to men. Worms are put down as the cause of death in 153 cases, one of which is ascribed to *Trichina spiralis*. The third class of deaths is from *constitutional diseases*, diathetic or tubercular, which were fatal to 88,504 persons in 1865. These diseases have this in common with the zymotic, that they are diffusive; and human tubercle is, even when introduced by inoculation, capable of inducing tubercular deposits in the organs of animals. The prevalence of phthisis in the armies of Europe is considered to be probably due in part to the inhalation of expectorated tubercular matter, dried, broken up into dust, and floating in the air of close barracks. Dr Farr remarks that to test this may be difficult, but the origin and propagation of the most fatal of all human diseases deserves full investigation. The inquiry should also extend to cancer and the other constitutional diseases, among which should perhaps be included diabetes. Among the deaths from constitutional diseases may be noted gout, as increasing every year. Gout is five times as common in men as in women, and is very rarely fatal under 35 years of age. To it, 361 deaths were attributed in 1865. Unlike gout, dropsy is most fatal to women; and the substitution of dropsy in women for gout in men after the age of 45 is worthy the attention of pathologists. Cancer is more than twice as fatal to women as it is to men. The mortality by all constitutional diseases is rather less than it was in the

* In the National Returns, all cases of fever are set down as Typhus, which is thus made to include pure Typhus, with blood-spots (*petechiae*) on the skin, which is exceedingly fatal (more than 20 per cent. of the cases in the London Fever Hospital proving fatal), is generated in crowded populations, and is very infectious; Typhoid or Typhoid Fever, which is endemic, is characterised by an eruption of rose-red spots on the skin, and by ulceration of Peyer's glands, and is usually generated by the intestinal evacuations of typhoid patients, which should therefore always be submitted to the action of disinfectant agents (its mortality in the London Fever Hospital is rather less than 20 per cent.); and, lastly, Typhina, which is commonly known as *relapsing* or *famine fever* (it is epidemic and infectious in times of scarcity and famine, and is comparatively harmless, the deaths amounting to only 24 per cent.). For the introduction of the terms Typhoid and Typhina, we are indebted to Mr Farr (see his 24th Annual Report of Births, Deaths, and Marriages in England, 1863, p. 214.

decade 1850—1859; and this is partly due to the decrease of the number of deaths referred to phthisis; still these deaths reached 53,734 in 1865, the greater part of them occurring in adults; and more than half the deaths of young women between 20 and 25 were caused by phthisis. The fourth class of diseases—the *developmental*—were fatal to 77,806 persons in England in 1865: 8791 infants born alive died from being premature; and other 22,436 died of debility before they were a year old. Besides 1333 deaths by puerperal fever, and 2490 ascribed to childbirth, 490 women died of specific diseases complicated by parturition. The deaths by ordinary diseases of the 560,000 *enccinte* women, constantly existing in the population of England, could not be entirely distinguished from the deaths of other women of the same age; of course they were subject to the same diseases as others, but probably the class of mothers belongs to what, in a certain sense, the insurance offices call select lives. The list of developmental diseases closes with the deaths of 28,709 persons from old age, 154 of the men and 402 of the women being of the age of 95 and upwards. Thus we reach the last class of deaths—the 17,374 persons who were destroyed by *violent deaths*; 15,232 by accident or negligence, 443 under circumstances bringing the case under the legal denomination of homicide, 1392 by suicide, 6 on the scaffold, and the remaining 301 not classed. These are the several ways in which 490,909 persons died in England in 1865.

Now let us see how many of the above diseases are more or less preventable, and how far we have already been successful in diminishing them. There are parts of England in which, for each 1000 persons living, there die annually only 15;* while there are other parts that, of each 1000 persons, 30 or more† die annually. The 15 and the 30 are said to be the respective death-rates of these places. The average London death-rate is 25; and the most common death-rate in country districts and small towns through all England and Wales is 20. The Registrar-general's Return, just published (January 1868), shewing the annual rate of mortality in the large towns of the United Kingdom for the year 1867, enables a comparison to be made of the death-rates in the last three years—1865 being the first year of the publication of these results. Thus, the average annual rate of mortality per 1000 persons living in the great cities in each of the years 1865, 1866, and 1867 respectively, was as follows: Birmingham, which is on one of the healthiest sites in the kingdom, 25, 24, and 24; the density of population (persons to an acre) in 1867, was 44. Hull, 27, 24, and 25; density, 30. Bristol, 24, 25, and 23; density, 35. Edinburgh, 23, 27, and 27; density, 40. Dublin, 26, 28, and 27; density, 33. Salford, 29, 29, and 29; density, 22. Glasgow, 33, 30, and 29; density, 87. Manchester, 33, 32, and 31; density, 81. Leeds, 31, 33, and 27; density, 11.

* In an article on 'Public Health,' in the *Quarterly Journal of Science* for January 1868, it is stated that at Sandown, in the Isle of Wight, which is thoroughly drained and well supplied with pure water, the death-rate for the last five years has been only 11 in 1000. As a contrast, we may take the village of Child's Hill, in the parish of Hendon, in which there is no efficient drainage, and where the open cesspools connected with the privies often overflow into the ditches and discharge their contents into the river Brent. Here, out of an entire population of 1000, there were 70 deaths last year (1867), mainly from epidemic typhoid.

† We have already mentioned that the death-rate at Liverpool not very long ago reached 70; see also the preceding note.

Liverpool, 36, 42, and 30; density, 96. The annual mortality in Sheffield, in each of the years 1866 and 1867, was 28 and 25; density, 10. In Newcastle-on-Tyne the annual mortality, in 1866 and 1867 respectively, was 32 and 31. The results for London, in each of the three years 1865—1867 respectively, were, annual mortality per 1000 of population, 25, 26, and 23; density, 40. In comparing the rate of mortality in one town with that of another, it should be borne in mind that of the English towns, Bristol, Leeds, and Liverpool have each a medical health officer. Birmingham, Hull, Salford, Manchester, Sheffield, and Newcastle-on-Tyne have no medical health officer, but most of these towns, however, have benefited from the efficacy of hygienic measures. It is obvious that if, by sanitary precautions, we could reduce all the death-rates to 15, or even to 20, an enormous saving of human life would result.* In the year 1865, Mr Simon suggested that the time was come for attempting to ascertain the amount of benefit to the public health that had been derived from the works of sanitary improvement—especially of drainage and water-supply—that had been already completed, and he was authorised to institute the inquiry, with the assistance of Dr Buchanan as an inspector. The result of the inquiry, which relates to 24 towns,† with an aggregate population of more than 600,000 persons, is now published, and we shall give a brief abstract of the results which have been obtained. The numerical results are given in the accompanying table (page 728), where A shews at each place in the list what difference there has been, since sanitary works were established, in the *general death-rate* in 10,000 of the population, this number being taken instead of 1000 to obtain more accurate numerical results. B gives the general death-rates of A, *minus* the inconstant influence which has been exerted by the chief infantile epidemics; and similarly E gives the means of eliminating from A the influence of the cholera epidemics of 1848—1849, 1854, and 1866. The columns C to G inclusive are for comparing the quantities of particular kinds of deaths caused in each of the places in the two compared periods. Such 'special death-rates,' used with caution, yield the most useful of all conclusions as to changes wrought in the public health.

From the table, which is fraught with the most valuable information, in the most condensed form, we learn that, omitting the influence of cholera, there has been a diminution in the death-rate in all but five cases, where the rate has been stationary. In four of the towns—viz., Cardiff, Newport (Mon.), Macclesfield, and Croydon—the reduction amounted to 24, 23, 20, and 18½ per cent. With regard to the *contagious diseases*, *small-pox*, which is capable of being rooted out by an efficient system of vaccination, is not noticed here, and *typhus fever* has scarcely occurred in the towns selected for inquiry. The time has hardly come for estimating the effect of works of sewerage and water-supply upon measles, scarlatina, and hooping-cough, inasmuch as epidemics of these diseases may revolve in long periods. *Measles* and *hooping-cough* seem, however, to have slightly declined. *Typhoid* has very much diminished with the ample supply of good water, and the

* As in the year 1865 (the latest for which returns are published), the population of England was 20,990,946, while the deaths were 490,909; the general death-rate for that year is 23·4. If this rate could have been reduced to 15, the number of lives thus saved in that year would have amounted to 176,324!

† Twenty-five towns were visited, but we have omitted Ottery St Mary, because it seems to have yielded no information.

SANITARY SCIENCE.

purification of the atmosphere from decomposing organic matter, by the abolition of cess-pools, by draining, &c. In Salisbury, Stratford, Croydon, and Merthyr, the annual death-rate from typhoid has diminished 75, 67, 63, and 60 per cent. respectively;

and in all the towns except three there was more or less diminution. In these exceptional cases, it was found that sewage gases were, by a defect of the outfall arrangement, forced into the houses.* *Diarrhœa* appears to have been reduced by puri-

fication of air and water. Removal of subsoil water has not affected it. While in three towns the death-rate from this disease has been diminished 50 per cent. or more, in Ashby it has increased 100, and in Rugby, 200 per cent. These anomalous results are ascribed to the prevalence of the disease in the respective workhouses. *Cholera epidemics* appear, says Dr Buchanan, to have been rendered practically harmless in the towns examined, as may be seen by the comparison of the death-rates per 10,000 in the three last epidemics :

Pulmonary phthisis has diminished in certain of the towns, and the diminution seems due to the drying of the soil, which has in most cases

accompanied the laying of main sewers; and the greater the influence of the sewerage in drying the subsoil is, so much the greater is the diminution of the death-rate from this disease. At Salisbury, it is 49 per cent. of its former rate; at Ely, 47; at Rugby, 43; at Banbury, 41; and at Worthing, 36. Failure to reduce consumption is

* Worthing is the town in which the increase of fever is greatest, and this need not excite surprise when we learn that on the side of the water-tower of the town is a shed containing the engine which performs the double duty of distributing the water to the houses and the sewage to the land. To enable this to be effected, there are two wells within 50 feet of one another, sunk in a porous soil, one for the reception of the sewage, and the other for the drinking-water. Moreover, the water-well is in bad condition, and the water-supply is neither constant nor sufficiently abundant. See the article 'Seaside Drainage—Worthing,' in *The Medical Press and Circular*, December 4, 1867. No arrangement for the propagation of typhoid could have been more ingeniously devised!

most observable either where the soil already contained little water, or where—the town water passing by the surface or in superficial drains—the deep drainage consisted of impervious pipes, laid down in compact channels, so that no extensive drainage of water could occur either through or alongside of them. It does not seem that the sewerage of towns, by the removal of excreta and house-slops, has acted to reduce the amount of their death-rate by consumption. *Diseases of the lungs* other than consumption have undergone no regular reduction. Dr Buchanan concludes this most valuable Report with the observation, that the progress made by the inhabitants of most of the towns in decency, cleanliness, self-respect, and morality, was at the least as striking as the improvement in their health, measured by the mortality returns.

In various articles on special disorders, as Scurvy, Small-pox, and Typhoid Fever, we have pointed out how completely they are under the control of sanitary or dietetic measures. In his excellent chapter 'On the Prevention of Diseases in the Army,' Dr Parke gives the following list of diseases, with the methods to be adopted for their prevention—viz.: (1) *Specific Diseases*—paroxysmal fevers, yellow fever, cholera, typhus exanthematicus, bubo plague, typhoid fever, relapsing fever, bilious remittent fever, eruptive fevers, erysipelas, hospital gangrene; and (2) *Non-specific Diseases*—dysentery and diarrhoea, liver disease, insolation, phthisis, scurvy, military ophthalmia (gray granulations on the palpebral conjunctiva), and venereal diseases.*

It is the miasmatic diseases which form the first order of the class of zymotic diseases, which seem most under our control. We have shewn in a previous page that recent researches tend to shew that various of these diseases owe their origin to fungi. We shall conclude this imperfect sketch of the history, progress, and results of sanitary science with a history of the recently-discovered *cholera-fungus*, and with a notice of the other recent scientific investigations regarding the nature and prevention of this disease (which may be regarded as a supplement to the article CHOLERA). At the international congress held last Easter (1867) at Weimar, the cholera-fungus was the great centre of interest. The subject had been investigated by Professors Hallier and De Bary, two of the leading German mycologists, and the latter drew up a Report, the following abstract of which is given by Mr Simon†: 'Both observers find in cholera evacuations, and in the intestinal mucus of the dead body, definite organic structures, zoogloea, consisting of excessively fine granules, clustered more or less densely in the interspaces of a jelly, which more or less abundantly surrounds them. The granules divide and subdivide themselves, to form beaded threads, which interlace, in immense numbers, into felted masses in the mucus. The further develop-

ment of these organisms has yet to be determined. Dr Thomé, by sowing them, has got, after some time, larger, round, cell-like bodies, which rapidly multiplied, and also abundant filamentous fungi (*cylindro-tenium*), on which grew cylindrical spores, capable of developing again to filaments. Views as to the mutual relations of these cells, filaments, and spores, are for various reasons to be expressed only with reserve; and the study of them is so immensely difficult, that definite results cannot at once be expected. The significance of these fungi would be greatly increased if they should be shewn to exist in the blood as well as in the bowels of the sick; but this, though from some inquiries it seems probable, must at present be deemed questionable.' It has been since ascertained that this fungus requires a high temperature (86° to 112° F.) for its fructification, and therefore cannot be of European origin. 'The doctrine of the cholera-fungus,' says Mr Simon—'the alleged discovery that the specific zymosis of cholera, the bowel-fermentation in respect of which it is contagious, has essentially associated with it, and perhaps as its immediate cause, a definite multiplying organic form—is not only of the utmost philosophical interest, but, should it be substantiated, may also, hereafter, be found capable of very important practical application. For, as one reflects on the doctrine in all its bearings, specially, as one considers Professor Hallier's conjecture (based on botanical considerations), that perhaps the *cylindro-tenium* is originally a blight of rice, something like a clue is for the first time suggested for investigations, which may hereafter conduce to the prevention of cholera in its eastern centres of origination. But for us in Europe, meanwhile, the doctrine may be absolutely sterile of results. In its broad signification, indeed, the discovery would not be a surprise to pathologists. The possibility has for some years past been recognised, that perhaps every fermentatory or putrefactive change of organic material has with it, and possibly as its cause, a characteristic molecular living thing; and however sure it may have become, that the choleraic zymosis answers to that possibility, it remains yet untried whether disinfection (which, after all, is but a doubtful resource) can deal better with the process on that basis, than on the purely chemical basis which has hitherto been the ground of our proceedings.'

'It cannot,' adds the same high authority, 'be too distinctly understood that the person who contracts cholera in this country is *ipso facto* demonstrated, with almost absolute certainty, to have been exposed to excremental pollution; that what gave him cholera was (mediately or immediately) cholera-contagium, discharged from another's bowels; that, in short, the diffusion of cholera among us depends entirely upon the numberless filthy facilities which are let exist, and specially in our larger towns, for the fouling of earth, and air, and water, and thus,

* In connection with diseases or affections which may be totally, or in a very great measure prevented, is short-sightedness. Dr Cohn, of Breslau, has examined the eyes of 10,060 school-children, out of which number 1730, or 17·1 per cent, were found to be short-sighted. No village-children were affected until they had been at least half a year at school. Dr Cohn attributes the evil, in a great measure, to the bad construction of the school-benches, which force the children to read with their books close to their eyes, and with their heads inclining downwards.

† A much fuller abstract (by Dr Buchanan) of Professor Hallier's recent researches into the natural history of the cholera contagion, as contained in his pamphlet, entitled *Der Cholera-Contagion: Botanische Untersuchungen, Aertzen und Naturforscher mitgetheilt*,

1867, is given in pp. 512—515 of the Appendix to Mr Simon's Ninth Report, to which that able pathologist has added a most instructive note on the earlier microscopic observations that had been instituted, especially by our own countryman, on the cholera evacuations. On the subject of cholera the reader should also consult Dr Farke's *Sanitary Report (Army Medical Department) for 1865* (published in 1867), in which he discusses the recent additions to our knowledge of (1) The specific cause of cholera—the cholera-fungus; (2) The spread of cholera by intercourse; (3) Its communication by the so-called premonitory diarrhoea; (4) Its spread by the agency of water; (5) and its prevention by disinfecting the discharges by means of carbolic acid, sulphate of iron, and salts of zinc.

SAN JUAN DE LA FRONTERA—SARAGOSSA.

secondarily, for the infection of man, with whatever contagion may be contained in the miscellaneous outflowings of the population.

'Cholera, ravaging here at long intervals, is not Nature's only retribution for our neglect in such matters as are in question. Typhoid fever and much endemic diarrhoea are, as I have often reported, incessant witnesses to the same deleterious influence; typhoid fever, which annually kills some 15,000 to 20,000 of our population, and diarrhoea, which kills many thousands besides. The mere quantity of this wasted life is horrible to contemplate, and the mode in which the waste is caused, is surely nothing less than shameful. It is to be hoped that, as the education of the country advances, this sort of thing will come to an end; that so much preventable death will not always be accepted as a fate; that, for a population to be thus poisoned by its own excrement, will some day be deemed ignominious and intolerable.'

In conclusion, we may remark, that Mr Simon's Ninth Report for 1866 (published in 1867) is one of the most valuable contributions to the literature of cholera that has ever been presented to the profession. The history of this disease in England in 1866 is first given. This is followed by a series of scientific investigations on the following points: (1.) Examination of the degrees of success attained by different methods of *treatment of cholera* at Guy's, St Bartholomew's, the London, and St Thomas's Hospitals; (2.) Study of the successive *chemical changes* undergone by the body in cholera; (3.) Similar study, chiefly microscopical, of the successive *anatomical changes* of the affected body; (4.) Collection of facts as to the non-coincidence of local epidemics of cholera with such conditions of the local ground-water as are indicated by a foul state of the surface-wells. The results of these studies are given in the appendix. Unfortunately, the practical result of these inquiries is, that in cases of developed cholera 'our utmost power is but perhaps some very little ability of palliation, and in the treatment of incipient cholera competent physicians are not agreed that even here their art has much efficiency.' In contrast with the powerlessness of curative medicine, the power of preventing it is about the happiest possession of science. The evidence of Dr Buchanan and others clearly shews that cholera may be prevented by due attention to sanitary works, which provide for the prompt and complete removal of faecal impurities, and the plentiful supply of water which cannot have been exposed to this form of contamination. In addition to the works quoted in this article, we may refer those of our readers who wish to study this subject more fully, to the French treatises on hygiene by Becquerel, Levy, Tardieu, Vernois, and others. There is, however, no work on the subject in any language equal to that of Dr Parke, from which we should not have ventured to borrow so freely if we had not had the author's kind permission to do so.

SAN JUAN DE LA FRONTERA, a town of the Argentine Republic, the capital of a province of the same name in the extreme west of the Republic. The town, 660 miles north-west from Buenos Ayres, stands on the right bank of a river, also called San Juan de la Frontera, which rises in the Andes, and falls into the large salt lake of Guanacache. The province is as yet only very partially settled, but exports considerable quantities of fruits and wine. The chief seat of trade is this town, which had, in 1860, a pop. of 20,000, almost one third of that of the whole province.

SAN LUIS DE LA PUNTA, the chief town of the province of San Luis in the Argentine Republic,

is situated 445 miles west-north-west from Buenos Ayres, on a river, which falls into the large salt lake of Bevodero. S. has some trade in horses, hides, and furs. Pop. above 5000.

SAN MARCO IN LA MIS, a town of South Italy, in the province of Foggia, 18 miles north-north-east of Foggia. It has some trade in corn, wine, oil, and silk. Pop. (1861) 15,284.

SAN MATEO, a town of Venezuela, South America, in the department of Cumana, and 50 miles south-south-west of the town of that name. Pop. 7000.

SAN SALVADOR, or **BA'NZA**—the former being the Portuguese, and the latter the native name—a town of Africa, the capital of Congo (q. v.). It is 120 miles south-east-by-east from the mouth of the estuary of the river Congo, in a mountainous district near the source of the river Lelunda. Pop. 20,000.

SAN TA A'NNA, or **ANA**, a town of Central America, in the state of San Salvador, and 32 miles north-west-by-west from the town of San Salvador. Pop. about 10,000.

SANTA FE, a town of the Argentine Republic, on the right bank of the Salado, a large branch of the Parana, 250 miles north-west-by-north from Buenos Ayres. Pop. 15,000.

SANTA MARTA, a town of the Granadian Confederation, the capital of a province, on a bay of the Caribbean Sea, 400 miles east-north-east from Panama. There is a good harbour, defended by a castle and several batteries. Pop. 8000.

SARAGO'SSA, or **ZARAGOZA**, a city of Spain, the capital of a province of the same name, and formerly of the kingdom of Aragon. It stands on the Ebro, here a muddy stream, which divides the city into two parts, and is crossed by a noble stone bridge, built in 1437. The city has an imposing appearance from a distance, being adorned with numerous slender towers and spires; but the traveller, on entering it, finds it full of narrow winding lanes, instead of streets, although the houses—which are built of brick—are of most solid structure, and many of them are the palaces of a nobility who have now ceased to reside here. These buildings, rich in finely carved decorations and magnificent cornices, are now mostly inhabited by agriculturists of a rude class; their spacious courts converted into farm-yards, and filled with dung-heaps. Everything about the city indicates decay and poverty. S. was the Celtiberian *Salduba*, but received the new name of *Casarca Augusta* in 25 B. C., of which the present name is a corruption. It was a place of importance under the Romans, but there are few remains of the Roman city. S. was one of the first cities of Spain in which Paganism was generally renounced and Christianity adopted; it afterwards became rich in relics, to which miraculous powers were ascribed. S. was taken by the Moors in the 8th c., and recovered from them in 1118, after a siege of five years, during which great part of the inhabitants died of hunger. It was taken by the French in 1809, after a siege of eight months, and one of the most heroic defences recorded in the history of modern warfare. See **PALAPOX**. S. has a university, founded in 1474. It has two cathedrals, both interesting as specimens of architecture; but the older is in a simple and severe style; the modern one—that of *Nuestra Senora del Pilar*—is very ornate. The latter cathedral boasts of a pillar on which the Virgin descended from heaven, 40 A. D.—an event so strongly attested, that Diego de Astorga, primate

SARANSK—SEWAGE EARTH-CLOSET.

of Spain, on 17th August 1720, excommunicated all who even questioned it. Pilgrims flock from all neighbouring parts of Spain to this pillar and the image of the Virgin, which came down from heaven. S. suffered grievously at the hands of the French in 1809, and lost most of its treasures of art. It has a considerable trade in agricultural produce, mostly carried on by the Ebro; and manufactures of silks, woollens, and leather. Pop. (1860) 67,428.

SARA'NSK, a town of European Russia, in the province of Penza, and 80 miles north from Penza, at the confluence of the Saranga and Insara, feeders of the Sura. Pop. (1863) 12,738.

SATA'LIAH, another name of Adalia (q. v.).

SAUG'OR, a town of India, the chief town of the British district of the same name, is situated in a hilly tract, on the Bees or Bes, a feeder of the Jumna, in lat. 23° 50' N., and long. 78° 49' E. S. is the seat of a military cantonment and of a collegiate school. The elevation is so considerable, that the climate is moderately cool; but the cantonment is unhappily in a swampy and unhealthy situation. Pop. about 50,000, mostly Mahrattas.

SCI'CLI, a town of Sicily, in the province of Noto, on the small river Scicli, 21 miles west-south-west from Noto. The woollen manufacture is carried on. S. is supposed to be the ancient *Casmena*. Pop. (1861) 10,029.

SCOT AND LOT VOTERS. The old legal phrase *Scot* (Ang.-Sax. *scat*, pay) and *Lot* embraced all parochial assessments for the poor, the church, lighting, cleansing, and watching. Previously to the Reform Act, the right of voting for members of parliament and for municipal officers was, in various English boroughs, exclusively vested in payers of *Scot* and *Lot*.

SCRIBE, AUGUSTIN EUGÈNE, a French dramatic writer, son of a wealthy silk-merchant of Paris, was born in 1791. Educated for the legal profession, he soon deserted it for dramatic authorship. His first piece, *Les Dervis*, written by him in conjunction with Germain Delavigne (brother of Casimir Delavigne), was played in 1811, but till 1816 he cannot be said to have achieved a decided success. Since that time, pieces, chiefly vaudevilles, from his pen have followed each other with the most astonishing rapidity; and in such demand were they at the hand of theatrical managers, that S. established a sort of dramatic manufactory, in which numerous *collaborateurs* were constantly at work under his supervision. His plots are interesting, and his dialogue light and sparkling; and not a few of his pieces have been adapted for the English stage. S. also wrote various novels, and composed the *libretti* for a considerable number of well-known operas, including *Maaniello*, *Fra Diavolo*, *Robert le Diable*, and *Les Huguenots*. He was admitted a member of the French Academy in 1834, and died February 20, 1861.

SEMMES, RAPHAEL, American naval officer, was born in Maryland about 1810, in 1828 entered as midshipman in the sloop-of-war *Lexington*, and was employed in the service as passed midshipman and lieutenant until 1855, when he attained the rank of commander. In 1858, he was appointed Secretary to the Light-house Board; but resigned March 26, 1861, joined the naval service of the Confederate States, and was appointed to the command of the war-steamer *Sumter*. The career of Captain S. until the sinking of his famous ship, the *Alabama*, by the American war-steamer *Kearsage*, is described at length in the article **ALABAMA** in the

SUPPLEMENT. Captain S., with 13 officers and most of his men, was rescued from drowning by the yacht *Deerhound*, and brought to England, where he expected to take command of one of two rams built at Liverpool for the Confederates, but which were seized by the British government. Thus foiled, he returned to America, was included in the surrender of the Confederate forces, and afterwards elected Judge of Probate at Mobile, Alabama; but, being prohibited from exercising his functions by the Federal authorities, he was, in 1866, appointed Professor of Moral Philosophy in a southern university.

SERAI'NG, a town of Belgium, in the province of Liege, and between three and four miles south-west from Liege, on the right bank of the Meuse. It is a station on the railway between Namur and Liege, and is connected by a handsome suspension bridge with the village of Jemeppe, on the left bank of the Meuse. S. is a place of great activity, and contains a manufactory of steam-machinery, locomotives, &c., which is probably the largest in the world. This manufactory was established by an Englishman, John Cockerill, in 1816; the king of Holland, to whose dominions Belgium then belonged, joining him in the enterprise. After the revolution of 1830, Cockerill bought up the shares belonging to the king of Holland, and the works became entirely his own. On his death in 1840, a company was formed, called *La John Cockerill Société*, to which they now belong. They occupy the former palace of the Prince-bishops of Liege, which still forms their front, the extensive gardens behind it having been covered with buildings, where all the processes of machine-making are carried on. Forty or fifty tall chimneys are clustered on this spot. The town depends on these works for its prosperity. Pop. (1863) 21,853.

SEWAGE EARTH-CLOSET. In addition to the various arrangements noticed under **SEWAGE** for getting rid of the excreta unavoidably present in every dwelling-house, there is now coming into use an *earth-closet*, depending on a peculiar principle. In the cess-pool system, night-soil accumulates in a way and to a degree that render removal very noisome and repulsive: if this removal be delayed too long, the atmosphere of the house becomes tainted in an unwholesome degree. In the water-closet system, the refuse, when flushed with water, is carried off through a costly system of brick sewers, too often into a river, the water of which becomes sadly polluted thereby. In the former case, the soil may possibly be made available as agricultural manure; and in the latter case, a similar useful application may be possible, if the sewage in a liquefied state be so diverted as to be conveyed by pipes to fields or farms. But in the earth-closet system, the refuse is made innoxious almost from the first. Experience has shewn that *dry* powdered earth, whether field-mould or fire-ash, has a remarkable deodorizing effect on night-soil, doing that which no dilution by water is able to effect. The fact has been known more or less, for a long time, to chemists engaged in sanitary inquiries; but the Rev. Henry Moule, vicar of Fordington, in Dorsetshire, has pursued the subject to a successful issue, first for the benefit of villages, and then of towns, hospitals, barracks, and other places in which large bodies of persons congregate. Having found that 1½ lbs. by weight, or 1½ pints by measure, of dry earth is sufficient for each time of using the earth-closet, he has devised various modes of applying it.

The *commode* form is the smallest, for use in bed-rooms, sick-rooms, &c. Under the seat is a metal

SEWAGE EARTH-CLOSET.

pail, removable through a front door; while at the back, and above the level of the seat, is an earth-box, filled from the top. Either by a handle which pulls upwards, or by a lever hinge which makes the seat itself move slightly, a valve at the bottom of the earth-box is opened, and a definite quantity of earth falls into the pan. If the quantity is about as above stated, and if the earth be perfectly dry, the prevention of offensive odour is surprisingly complete. The earth-box will hold from 20 to 30 of these portions. The contents of the pail may be emptied at leisure, for they remain nearly inodorous from first to last. They may be either applied at once as a manure to garden or field, or may be kept in a heap under cover till wanted. One remarkable fact in this system is, that the same earth may be used two, three, or even seven times over, if it be well dried after each using; it becomes then exceedingly rich as a manure, and yet less offensive to the senses than what results from the use of cess-pools or water-closets.

The *single fixed closet* is adapted for use in the places usually occupied by a privy or a water-closet; indeed, the earth-measuring and delivering apparatus may be applied to most existing closets, as a substitute for the water-tank and pipes. Unlike the commode, there is a cell or vault instead of a pail beneath the seat; this cell may be four feet by three, and of a depth depending on the frequency with which it is intended to be emptied; the sides should be lined with cement, and the bottom paved with stone or asphalt. An existing cess-pool, emptied, cleaned, and perhaps made shallower, would in many cases be available. The mixture of refuse and earth might go on accumulating for a whole year, with very little appreciable odour. In places where a pit or cell cannot conveniently be made, a movable iron trough may be substituted, emptied more frequently.

Compound closets, for use in schools, barracks, and other places, may consist of as few as two or as many as twenty, placed side by side. There may be a great saving of material and construction; but the earth-apparatus must be applied to each separately.

Two important conditions apply to the success of this system—the obtaining of the earth, and the disposal of the deposit. Dr Mouat, Inspector-general of Jails in India, has caused experiments to be made which shew that dry earth is really better than any chemical disinfectants for removing all odour from night-soil. If earth is not readily obtainable, it may be supplemented by sifted ashes. Iron drawers or trays under a kitchen-range, portable dryers of various kinds, and fixed dryers, have been devised for drying the earth; this is a matter that can soon be brought into working order, if the system were adopted in other ways. Dry earth might be procured in the summer, and stored in a cellar or vault for winter use, just as we are wont to lay in a store of coals. No sand should be used with the earth and ashes; it is not suitable. No house-slops of miscellaneous kinds should be thrown down into the pail or pit; the deposit should not artificially be liquefied. The dry-earth system is applicable to urinals at railway stations and other places where the present existing system produces most offensive and unhealthy odours; but a peculiar adjustment of apparatus would be necessary.

The disposal of the deposit, like the obtaining of the earth, is more practicable in the country than in towns; for the simple reason, that fields are near at hand; and it is probable that country districts and large establishments will test the efficacy of the system before it is much tried in ordinary dwelling-

houses in towns. From twenty to thirty shillings per ton may be obtained for the refuse.

Many evidences have recently been afforded of the successful adoption of this system. Captain Armytage, governor of the West Riding Prison at Wakefield, stated, in 1867, that earth-closets have been placed in the cells of that building, with a manifest diminution of the unpleasant odour which used to pervade many sections of the prison during the existence of the water-closet system. A small kiln has been built for drying the earth, and a store for earth provided; the used earth is turned over and pulverised a few times during a month, and is then fitted to act as manure; and it is expected that this manure will gradually defray all the expenses incurred by the adoption of the system. In the Dorset County School at Dorchester, where a severe sickness was attributed by the medical men to the noisome effluvia from the school-privies, the earth-closet has produced a marked improvement. The same result has followed in a large private school in Sussex. In the villages of Halton, Buckland, Weston Turville, and Aston Clinton, on Baron Rothschild's estate in Buckinghamshire, the earth-closets have been adopted, with a complete removal of the offensive results of the former cess-pool system; the earth is used six or eight times over, becoming in the end a very rich manure; and one man and a boy, with a horse and cart, suffice for all the carrying and removal at the four villages. The Registrar-general of Births, Marriages, and Deaths, in his Quarterly Return for July 1867, speaks of the earth-closets as promising 'to be as useful in the departments of public health and national agriculture as the Rev. Edward Cartwright's invention is in the cotton manufacture.'

Arrangements have been made by the government for the adoption of the earth-closet system on a very large scale in India. In the hospitals, jails, and lunatic asylums of Bengal; in the jails of the North-west Provinces; in the dispensaries and prisons of the Punjab; in the jails of Oude, the Mahratta Provinces, Mysore, Coorg, and Hyderabad; in the *latrines* of some of the barracks and military stations—in all of these, the system is now adopted. The medical officers with one voice speak of the favourable result. The Secretary of State for India, in September 1867, made public a communication from Major Malleson, Sanitary Commissioner for Bengal, enclosing Reports which he had received from the various provinces concerning the earth-closet system. In one of these Reports, Dr Mouat, already mentioned as Inspector-general of Jails in India, went so far as to characterise the introduction of this system as 'the greatest public benefit conferred by a private individual, in a matter so essential to public health, with which I am acquainted.' The Council of India have very properly made a recognition of the services rendered, without any intention of profit, by the clergyman who has pursued this subject to a successful result.

The Metropolitan Association of the Medical Officers of Health recently (December 1867) devoted a special evening to the discussion of the comparative merits of the water-closet and dry-earth systems. Opinions were mostly in favour of the dry earth system in consequence of the readiness with which water-closets get out of order (especially in the dwellings of the poor), and thus become sources of grave danger. On this subject, Dr Parkee, in his latest annual report on hygiene (*Army Medical Reports, 1867*), observes: 'That the earth plan, which has been proved most useful in India, can be applied in England advantageously on a small scale, is certain; but it is still a question whether it is

SHAHJEHANPORE—SHAKERS.

applicable to our large towns on account of the large quantity of earth which has to be brought in and taken away.' It has been introduced into Lancaster with apparent success. On this subject, see *The Sewage of Towns*, papers by various authors, edited by John Hutchman (London, 1866).

SHAHJEHANPORE, a town of British India, the principal place of a district of the same name, North-west Provinces. It stands on the Gurrah, a feeder of the Ramgunga, 94 miles north-west from Lucknow. Pop. about 63,000.

SHAKERS, the name commonly given to a small religious sect existing in the United States of America. The proper or official description of this sect is the United Society of Believers in Christ's Second Appearing; but its members seem to have accepted the designation of Shakers, though it was originally applied to them in ridicule, on account of certain rhythmical movements of the hands and arms which form part of the ceremonial of their worship. Though the Shaker Societies are found only in the United States, their creed had an English origin. The founder of the sect, in whose person they believe that Christ has appeared a second time, was an Englishwoman, named Ann Lee, a native of Manchester, who emigrated to New York with a small band of disciples, shortly before the outbreak of the revolutionary war.

Ann Lee was the daughter of a blacksmith, who lived in Toad Lane in Manchester; a very poor man, who gave her no education, and sent her while a mere child to work in a cotton-mill. She seems to have been a violent, hysterical girl, ambitious of notice, and fond of power, and to have always possessed, in virtue of her strong will and vehement temper, a great deal of influence over the people around her. She married, while very young, a blacksmith named Stanley. She had four children, all of whom died in infancy—to this, perhaps, may be ascribed the preference of the celibate to the married life, which she ultimately raised into a part of her religious system. She became one of the earliest believers in a prophetess, who appeared about a hundred years ago, in the town of Bolton-on-the-Moors, in Lancashire—a poor woman, named Jane Wardlaw, the wife of a tailor, who believed she had 'received a call' to go forth and testify for the truth. The burden of Jane Wardlaw's message was, that the end of all things was at hand, that Christ was coming to reign upon the earth, and that his second appearance would be in the form of a woman, as prefigured in the Psalms. In subordination to this, she took up several of the tenets of the Society of Friends, to which she and her husband originally belonged; especially, she raised her voice against war and against profane swearing. Her followers believed that she was filled with the Holy Spirit; they received her utterances as the voice of God; and she acted as if all the powers of earth and heaven had been given into her hands. Ann Lee, on her conversion, began to preach the same message in Toad Lane and the adjacent streets of Manchester; but she soon went beyond her teacher, and gained the leadership of her co-believers for herself. It happened that she was brought before a magistrate, charged with an obstruction of the streets, caused by the crowd collected to hear her preach, and she was sent to the Old Bailey Prison in Manchester. When she came out of prison, she gave forth, that one night, a light had shone upon her in her cell; that the Lord Jesus stood before her; and that He became one with her in form and spirit. Her pretension was, that Christ was come to reign in her person. It was favourably entertained by the followers of Jane Wardlaw; and they

acknowledged her as their Head, or Mother, in place of Jane, whose pretensions had never gone so far. She found, however, that among her neighbours and fellow-workers, her claim to be the Bride of the Lamb, the Queen described by David in the Psalms, excited only jeering and ridicule; and she received a revelation that she should seek in America a home for herself and her few disciples—that it was in America that the foundations of Christ's kingdom were to be laid. So she went to New York, accompanied by seven disciples—five males and two females. Her husband also went with her; but he seems to have had no faith in her, and he left her soon after their arrival, in consequence of one of the features then introduced into her system. This was the practice of celibacy, which she had not previously enforced upon her followers, though she had enjoined it as a duty. Her teaching was, that men called into grace must live as the angels do, among whom there is no marrying or giving in marriage; that no form of earthly love could be allowed in the Redeemer's kingdom. Finding a populous city unfavourable to her designs, she removed, with her followers, first to Albany, then far into the wilderness to Niskenna, and there founded the settlement which still exists, of Water Vliet. It was in the spring of 1780—when she had been three years and a half at Niskenna, looking for new believers to come in, but making no attempt to win them—that the first American converts joined her Society. A revival had taken place at Albany, and had spread through the surrounding districts; and from Hancock and New Lebanon a deputation was sent to Niskenna, to see what light its inhabitants enjoyed as to the way of salvation. The deputation consisted of Joseph Meacham and Lucy Wright—subsequently the heads of the Shaker Society. These persons became believers in Ann Lee; and through their agency, other converts were won, and a Shaker Society established at New Lebanon. Towards the close of 1780, the revolutionary war being then in progress, notoriety was given to Ann Lee's pretensions, through an incident seemingly unfavourable. Owing to her British origin, her denunciations against war, and her refusal to take the colonial oaths, Ann was imprisoned for some time at Poughkeepsie, on suspicion of being a British spy. Before she was let out of prison, in December 1780, all the colonies had heard of 'the female Christ.' In the following year, she started upon a missionary tour through New England and adjacent colonies; she found the people everywhere curious to see her, and she made not a few converts. She did not return to Water Vliet till September 1783; and about a year after, she died. Her death was a surprise to many of her followers, who believed that she was to live among them for ever; but her successors—the Joseph Meacham and Lucy Wright already mentioned—to whom, on her death-bed, she had made over the headship of the Society, were ready with a theory accounting for it. 'Mother Ann,' they said, could not die, and was not dead, and had not ceased to live among her people. She had only withdrawn from the common sight; she was still visible to eyes exalted by the gift of grace; she had cast the dress of flesh, and was now clothed with a glory which concealed her from the world. So it would be with every one of the saints in turn; but the spirits of those who 'passed out of sight' would remain near and be in union with the visible body of believers. This explanation was generally accepted, and has become a vital part of the Shaker creed.

By Joseph Meacham and Lucy Wright, the successors of 'Mother Ann,' the S. were gathered into

SHAKERS.

settlements, ten in number; and a covenant was drawn up embracing the chief points of their creed, and of the social system since associated with it. Their head was, of course, 'Mother Ann'—that is, Christ—of whom Joseph and Lucy were temporarily the representatives; elders and deacons, male and female, were appointed; the institution of celibacy was confirmed; and a community of goods was introduced. On the death of Joseph Meacham in 1796, 'Mother Lucy' became the sole head of the Society, and she governed it with ample powers for 25 years. She named a female successor with the title of Elderess; and the name of 'Mother' has not, since that time, been applied to the female head of the community. The present female head is Elderess Betsy (Betsy Bates); the chief elder is Elder Daniel (Daniel Boler); and the ruling spirit of the Society, the official preacher and expositor of Shaker doctrine, is Elder Frederick of New Lebanon (Frederick W. Evans), who is by birth an Englishman. The S. were, at the census of 1860, more than 6000 in number, included in 18 societies; of which three are in the state of New York, four in Massachusetts, two in New Hampshire, two in Maine, one in Connecticut, four in Ohio, and two in Kentucky. Their numbers have increased considerably since 1860; the influence of their opinions has greatly increased; and the 18 separate settlements continue to form a united and peaceful Society.

Their doctrine has been to some extent developed as well as systematised since the death of 'Mother Ann.' They believe that the kingdom of heaven has come; that Christ has come upon earth a second time, in the form of 'Mother Ann,' and that the personal rule of God has been restored. Then they hold that the old law has been abolished, and a new dispensation begun; that Adam's sin has been atoned; that man has been made free of all errors except his own; that the curse has been taken away from labour; that the earth and all that is on it will be redeemed. Believers, on going 'into union,' die to the world, and enter upon a new life, which is not a mere change of life, but a new order of being. For them, there is neither death nor marriage; what seems death is only a change of form, a transfiguration which does not hide them from the purified eyes of the saints; and in union, as in heaven, there is no marrying or giving in marriage—the believer owes love to all the saints, but his love must be celibate in spirit and in fact. The believer, living in union, is in heaven. The S. believe that the earth, now freed from the curse of Adam, is heaven; they look for no resurrection besides that involved in living with them in 'resurrection order.' The believer, upon entering into union, leaves behind all his earthly relationships and interests, just as if he had been severed from them by death. And since to be in union is heaven, the S. hold that no attempts should be made by them to draw men into union: God, they say, will draw to them those whom he has chosen at his own time. Those who have 'passed out of sight' are still in union; and the S. live in daily communion with the spirits of the departed believers. The belief in a communion with angels and spirits, is no mere theory; it has a most important influence upon their lives; they profess to be more familiar with the dead than with the living. It being the work of the saints to redeem the earth from the effects of the curse, labour is a sacred and priestly function, especially when bestowed in making the earth yield her increase, and in developing her beauty. It should be done in a spirit of love; the earth, they say, yields most to those who love it; and love and labour will in time restore it to its primitive state.

According to Mr Dixon, they bestow upon their gardens and fields the affections which other men bestow upon family or worldly goods. Their country they regard only as it is a part of the earth, which they love, and as the favoured land in which God's kingdom is first to be established. In its politics and its fortunes, they take no interest; and, indeed, their whole system is a protest against the existing constitution of society, as well as against the ordinary lives of men. Consistently with their belief in the second appearance of Christ in the form of a woman, the S. seem to believe that there is a female as well as a male essence in the Godhead—in the motherhood as well as the fatherhood of God.

A Shaker settlement is, for convenience, divided into families, consisting of the brothers and sisters, who live in the same houses, each governed by an elder and an elderess. There are two orders of members, Probationers and Covenanters—that is, novices and full members. It is on becoming a covenanter that the Shaker puts his property into the common stock. On entering upon residence, he becomes subject to all the rules of the Society; but he is free—whether a covenanter or a probationer—to leave the body whenever he pleases. Both men and women wear a prescribed dress. The men wear a sort of Arab sack, with a linen collar and no tie; an under-vest buttoned to the throat, and falling below the thighs; loose trousers, rather short; and a broad-brimmed hat, usually of straw. The women wear a small muslin cap, a white kerchief round the chest and shoulders, a skirt dropping in a straight line from the waist to the ankle, white socks, and shoes. Some latitude is allowed as to the materials of the dress. Men and women, it is said, have the look of persons at peace with earth and Heaven. 'Apart from a costume,' says Mr Hepworth Dixon, 'neither rich in colour nor comely in make, the sisters have an air of sweetness and repose, which falls upon the spirit like music shaken out from our village bells.' [*New America*, by W. Hepworth Dixon (Lond. 1867), from which the materials of this sketch have in a great measure been derived.] All labour with their hands, both men and women; but the latter do only indoor work. Every man, whatever his rank in the church, follows some manual occupation, and most of them have more than one. Working not for gain, but with loving care, and with the sense that they are exercising a priestly function, the S. are unrivalled among their neighbours in the arts to which they apply themselves, especially the culture of their land, and the production of fruits and flowers. They pay great attention to ventilation and to all sanitary conditions; they live almost entirely upon the produce of the soil, and drink only water; they employ no doctors, and take no drugs, and are, nevertheless, among the healthiest of communities. Their Society is recruited mostly by young men and girls; but occasionally, married persons with their children come 'into union,' and make, it is said, 'very pretty Shakers.' Husbands and wives, when they have come 'into union,' become as brothers and sisters: it would be thought a weakness, says Mr Dixon, and almost a sin, for them to feel any personal happiness in each other's company—they live for God alone, and their love ought to be shed on all the saints alike. The education of the children attached to the Society is the work of the sisters, and they do it exceedingly well. The brothers and sisters take their meals in a common room, eating at six in the morning, at noon, and at six in the afternoon. Their meals are taken in silence, any direction that has to be given being given by a gesture or in a whisper. In their church-service, music bears a prominent part; the hymns and chants which are used being

all of Shaker origin, communicated to believers in dreams and reveries by the spirits with whom they have communion. The spirits, it is said, shew no great regard for rhyme or grammar.

SHINGLES (probably derived from Lat. *cin-gulum*, a belt) is the popular name for the variety of *Herpes* (q. v.) which is known as *H. zoster*.

SHIP-BROKER, INSURANCE BROKER. A ship-broker is a person employed in the buying and selling and freighting of ships. His duties include adjusting the terms of charter-parties and bills of lading, settling with the master for his salary, collecting freights on goods brought into port, arranging with passengers for the terms of their passage, and generally managing all business transactions occurring between shipowners and the shippers or consignees of goods. The charges made by ship-brokers are generally about two per cent. on their gross receipts. Ship-brokers have been ruled not to be within the acts for the regulation and admission of brokers.

The business of an *insurance broker* is usually combined with that of a ship-broker. Marine insurance is in Great Britain to a large extent transacted by brokers. Those who insure are in most cases capitalists, who are known to the broker as persons prepared to undergo any risks which he recommends to them. The broker, who has a list of persons ready at a moment's notice to underwrite a policy, is the mutual agent for both parties. He procures the subscriptions of the underwriters, arranging with them the rate of premium and conditions of the risk, receiving from them the amount of their respective subscriptions, in the event of loss; and, when such loss is partial, arranging the proportion to be recovered from the different underwriters. An insurance broker charges as profit five per cent. on the premium, and one-half per cent. deducted from all claims recovered from the underwriters. An insurance broker is personally liable to the underwriters for the amount of the premium, but incurs no liability to make good the amount insured to the owner of the ship and goods, who, in case of loss, must look to the underwriter alone for indemnification.

SHIS'DRA, or JIS'DRA, a town of European Russia, in the government of Kaluga, and 80 miles south-west from Kaluga, on the Shisdra, a branch of the Oka. It has manufactures of woollen cloth, glass-works, iron-works, tanneries, oil-factories. Pop. (1863) 10,083.

S'YLLOTH, a town and watering-place of England, of quite recent origin, in the county of Cumberland, at the terminus of a branch of the North British Railway, 20 miles west-north-west of Carlisle, is picturesquely situated on the Solway. The port is of growing importance, and possesses a good stone dock, with an area of five acres, having a fine jetty, 1000 feet long, projecting into the sea. S. is much resorted to for sea-bathing, the climate being mild and salubrious, and considered highly favourable for those affected with pulmonary complaints. The mean annual temperature is 49°, being the same as that of Worthing (q. v.) on the south coast of England, and only 1° below that of Torquay. According to the Registrar-general's returns, the mean average death-rate in S. for ten years is only 10.2 per 1000. S. is of easy access from all parts of England by railway, and steamers ply at stated intervals to and from Liverpool, Dublin, Belfast, and the Isle of Man.

SIMMS, WILLIAM GILMORE, American author, was born at Charleston, South Carolina, April 17,

1806, of Irish extraction. He made verses at the age of seven; and during the war of 1812, celebrated in rhyme the exploits of the American army and navy. Left in charge of his grandmother at Charleston, he was placed with a druggist; but at 18 began the study of law; was admitted to the bar at 22; published *Early Lays and Lyrical and other Poems* (1827); and became (1828) editor of *The City Gazette*, and published *The Vision of Cortes, Cain, and other Poems* (1829), and *The Tri-Colour*, a poetical glorification of the French revolution (1830). In 1832, his paper, opposing nullification, failed; and he lost his wife, father, and grandmother, and took refuge in New England, where, at Hingham, Massachusetts, he wrote his best poem, *Atalantis, a Story of the Sea* (1833); and the same year, *Martin Faber*, the story of a criminal. From this time, he poured out rather than wrote poems, novels, histories, and biographies in rapid succession, which may best be classed in groups. Of poems, he published *Southern Passages and Pictures* (1839); *Donna Anna* (1843); *Grouped Thoughts and Scattered Fancies* (1845); *Lays of the Palmetto*—ballads of Southern heroism in the war with Mexico (1848); *Poems Descriptive, Dramatic, and Legendary* (1854); *Aretyos, or Songs and Ballads of the South* (1860). Of dramas—*Norman Maurin, or the Man of the People*; *Michael Bonham, or the Fall of the Alamo*; and a stage adaptation of *Timon of Athens*. Of prose romances of the imagination—*The Book of My Lady* (1833); *Carl Werner* (1838); *Confession, or the Blind Heart* (1842); *Castle Dismal* (1845); *The Wigwam and the Cabin*, two series (1845, 1846); *Marie de Berniere* (1853). Of historical romances—*The Yemassee* (1835); *Pelayo* (1838); *Count Julien* (1845); *The Damsel of Darien* (1845); *The Lily and the Totem, or the Huguenots in Florida* (1845); *The Maroon, and other Tales* (1855); *Vasconcelos* (1857); *Cassique of Kiawah* (1860). Of revolutionary stories—*The Partisan* (1835); *Mellichamp* (1851); *Katherine Wallon* (1851); *The Scout* (1841); *The Kinsman, or the Black Riders of the Congaree* (1841); *Woodcraft* (1855); *The Foragers* (1855); *Eutaw* (1856); these five being stories of the war in the Carolinas. Of local tales—*Guy Rivers* (1834); *Richard Hurdis* (1838); *Border Beagles* (1840); *Beauchamps* (1842); *Heley Halsey* (1845); *The Golden Christmas* (1852); *Charlemont* (1856). His other works comprise a History of South Carolina; South Carolina in the Revolution; Lives of General Marion, Captain John Smith, Chevalier Bayard, General Greene; Civil War in the South; American Loyalists of the Revolution; Views and Reviews of American Literature; The Morals of Slavery, &c. Residing in South Carolina during the War of Secession, he sustained the Southern cause in a weekly newspaper, and had his house and library wrecked by Federal soldiers. Of his various and voluminous works, some are of high excellence.

SIMPSON, SIR JAMES YOUNG, was born at Bathgate, Linlithgowshire, in 1811. He early shewed a peculiar talent for medical observation and research; and in the prosecution of his professional studies at the University of Edinburgh, so attracted the notice of his teachers as to inspire all of them with an active interest in his future career. He graduated as doctor in medicine in 1832, on which occasion his inaugural thesis won the highest admiration. Professor Thomson chose him as his professional assistant, and employed him in the preparation of his course of lectures on General Pathology. During the illness of the professor, Mr S. supplied his place in the lecture-room with unusual skill and address. He now began professional practice on his own account; and in 1840, succeeded Professor Hamilton as Professor of Midwifery in the University of

Edinburgh. This position he has held with yearly enhanced distinction, and by the rigidly scientific, while popularly attractive, character of his prelections, has contributed greatly to the renown of the Edinburgh school, both at home and abroad. He has been indefatigable, amid the distracting cares of an extensive practice, in promoting the scientific perfection of his art; and his two volumes of *Obstetric Memoirs*, edited by Drs Priestly and Storrer, contain the fruits of much patient and ingenious research. The discovery by which he will be more particularly remembered, however, is that of the anæsthetic virtues of chloroform. The so-called sulphuric ether had been employed in America by Morton to produce anæsthesia during labour; but to S. belongs the credit of having, in 1847, first introduced to the scientific world the far safer, more certain, and now universally adopted agent of chloroform. Another innovation which surgical practice owes to Professor S. is the stoppage of hæmorrhage by Acupressure (q. v. in SUPPLEMENT). In his own peculiar field of obstetrics, his improvements on the old methods of practice are numerous and valuable; while his contributions to antiquarian research would of themselves create an independent reputation in that field. Besides the *Obstetric Memoirs* already mentioned, he has published a volume on Acupressure; and many papers and notices read before the Royal and Antiquarian Societies of Edinburgh. Among these may be enumerated: *Antiquarian Notices of Leprosy; On the Contagiousness of Cholera; Ancient Roman Medicine Stamps; Was the Roman Army provided with Medical Officers? Notes on some Ancient Greek Vases for containing Lykion, &c.; On Syphilis in Scotland; &c.* His scientific services have been recognised by nearly every medical association in either hemisphere; while his professional distinction has secured for him (1866) a baronetcy from the Queen. [He died 6th May 1870.]

SINCERE BRETHREN, or **TRUE FRIENDS**, is the name of a semi-religious, semi-scientific Mohammedan order, the beginnings of which are shrouded in obscurity, but which, about 970 A.D., manifested its existence by one of the boldest and most comprehensive literary undertakings—viz., an encyclopædic treatment of philosophy, theology, science, ethics, and metaphysics, in a series of no less than fifty-one treatises. Under the head of **MOHAMMEDAN SECTS**, and more especially under **MOTAZILITES**, mention has been made of that immense religious struggle that arose but a few generations after Mohammed, in the bosom of Islam, bringing forth sect after sect; and which, under whatever name and war-cry, simply denoted the reaction of the thinking minds against the dead-weight of dogmas and formulas, such as the successors of the Prophet tried in his name, and often enough in direct contradiction to his explicit dicta, to impose upon the Faithful. What the Motazilites had attempted was the reconciliation of scientific speculation, as it had irresistibly grown up at the first contact of the Arabs with Greek literature, with the religious dogma of Islam. This new period of development of Arabic culture, which chiefly characterises the epoch of the first Abbasside rulers, however, was of no long duration. The representatives of the 'orthodox' schools, who would not hear of reconciliation, but insisted all the more uncompromisingly upon the most literal interpretation, dexterously used against them those same weapons of dialectics which their adversaries themselves had first taught them how to wield. Setting to work with proper systems and methods, they soon built up a scholastic edifice of theology, not easy to be attacked without the most direct

outspokenness; and from this the new schools, the terror of the califate strong upon them, shrank. It was thus that the Motazilites soon disappeared from the arena. But their labours had not been in vain. Silently and by small degrees this new and mysterious union of the Sincere Brethren arose. Though widely spread, their schools, their houses of assembly, their rules, their doctrines—everything remained, for we do not know how long, a profound mystery; and apart from that which they themselves have thought fit to reveal of it, neither ancient nor modern investigation has been able to discover many traces of their inner organisation and activity. Not even many of their names have come down to us, though the 'treatises' they have left point to a multitude of authors, and to many stages of development. The tone of these treatises is much more free, and their entire tendency more radical than that of any of the books of their predecessors. Yet, the desire not to offend the less advanced in religious matters, and above all, to reunite rather than to make the breach wider, is perceptible in their endeavour to use what Koranic quotations and traditions can be pressed into the service of free thought, by often very unnatural processes of allegory and mysticism.

Before speaking of the treatises themselves, we shall briefly summarise what can be gathered as to the mutual relations of the brethren of this secret lodge, and the aims of their association. There is special mention made of the 'secret doctrine' which the Brethren should communicate to each other in their houses of assembly at those 'stated periods,' at which no stranger was to be admitted on any condition. The principal subjects towards which their conversation was to be directed were to be the knowledge of the soul or psychology, the knowledge of the action of the senses and the things perceptible through them, the contemplation and investigation of the mysteries of the sacred books, of the prophetic revelations, and the ideas contained in the divine laws. Their attention was further to be directed towards the four 'mathematical' sciences—arithmetic, geometry, astronomy, and (musical) composition. But the chief subject of their investigations should be the knowledge of divine things, which are the end and aim of all study. The most catholic spirit was to prevail among them with regard to the various sciences, systems, or books; since 'our own system comprises all, without exception, and includes all science.' 'The speculations of our school extend simply to all things—the sensual and the intellectual—from the moment of their beginning to their end, according to their outer and inner life—that which is palpable and clear about them, and that which is hidden and secret—the Truth, in fact. For the true essence in everything is derived from one primeval origin and general cause, since there is but one world and one supreme mind, to which all the most manifold phenomena, species and kinds, and divisions, are to be traced back.' With these words, the encyclopædic tendency of the lodge and their essays is best characterised.

All their knowledge they traced back to four sources—as indeed this number seems to have played a very considerable part in all their divisions—as follows: 1. 'The books that are known by the names of the sages and philosophers, in as far as they belong to mathematics and natural history.' They do not indicate them further; but it is easy to see from the treatises themselves that they allude to the translations of Greek works bearing the names of Pythagoras, Aristotle, Euclid, Ptolemy, Porphyry, &c. 2. 'The revealed writings derived from the prophets,' such as the five Books of

Moses, the Gospel, the Psalms, the Koran, and other writings of prophets who had received their contents through inspiration by the angels and the 'deep mysteries hidden in these books. 3. 'Books treating of nature'—i. e., that describe and represent the things now in existence—the celestial circles, the motions of the stars, the transformation of matter, the individual species and kinds of animals, plants, &c. All these things point to abstract ideas and subtle mysteries of which men in general saw but the outside, ignoring the mysterious art and meaning of the Creator hidden within. But if, in this third division of the sources, the power of the mysterious and of spiritualism must needs have become very strong, it seems to have ruled absolute in that most mysterious and obscure of all sources, the fourth—viz., 'the divine books, or the books on the divine things, written by the angels from the tablet of Fate, upon which all the divine decrees regarding the world and man are inscribed. These contain all that refers to substances, species, kinds, and orders of the different souls; their actions, destinies, metamorphoses, phase after phase, the heavenly conjunctures and periods, &c.' For this the Koran was quoted: 'And upon the Arap' [the division between heaven and hell] 'there will stand men, who will recognise every one by their distinguishing mark.' These men, however, are souls who take a higher degree than other men, like the prophets and martyrs, or the elect among the believers and learned, or the angels who appear in human shape.' And that there might be no mistake as to the members of the secret brotherhood being alluded to in this passage, another passage from the same sacred volume is adduced, which reads: These are the men who live in houses which God has permitted to be erected, that His name might be praised therein, in which men proclaim His praise both morning and evening, whom even neither commerce nor trade intercourse keeps from the remembrance of God and the solemn fulfilment of the duty of prayer. 'This is the state of our brothers, the highly meritorious, the highly honoured.'

The supreme (outward) duty of the brethren was to support one another in case of need. Men are divided into four classes—those who have wealth without knowledge; those who have knowledge without wealth; those who have both; and those who have neither. And this at once points to the necessity of mutual support. Envy and ill-will are seriously reprobated, and here the ethical portions of the Koran and the Sunnah are appealed to. But these fundamental principles are further explained and detailed in the rules almost step by step; and it is shewn how each of the four classes named is to make its support of the Brethren more effective. Everything should be directed for the benefit of the soul, not of the body; everything for the future, nothing for this world. Moral qualities are the highest gift of heaven, and the characteristic sign of the angels and the blessed in paradise—a wise and happy way of comforting the poor of the community, who, by moral purity, may lift themselves to the same purity as the best and richest among the Brethren. In order further to prove how the soul is capable of the highest perfection by degrees, the various ages and stages of man are enumerated, and the gradual progression of all faculties is dwelt upon according to the 'strength of the soul.' The fourth degree is characterised as the angelic quality of the soul, which is obtained at fifty, and which prepares the way to everlasting life, and to the full separation from matter. To this succeeds the 'power of ascension,' whereby the member mounts

up into the world of the spiritual heavenly beings, so that he foresees clearly the 'things of the end,' such as the resurrection, the last judgment, the dispersion, the meting out of rewards and punishments; how, further, 'the path is to be crossed, how he escapes the fire, enters Paradise, and becomes a denizen of the highest realms with the Father of all mercies.' And for this consummation, many passages in the Koran and the Gospel are adduced—no less than the words of Socrates on the day of his taking the hemlock; of Pythagoras at the end of his Golden Epistle, &c.

The encyclopædia of treatises which this secret association has left as the monument of its existence, was first compiled at Basrah about 1000 A. D.; but has (save one often reproduced chapter, called 'The Contest between Man and Animal') never been printed. The 61 treatises are divided into four classes: 1, the 'Mathematical,' in 13 dissertations or treatises; 2, the 'Physical,' in 17; 3, the 'Origins' of mental activity, or the thinking soul, in 10; and 4th and last, 'The Divine Law,' in 11 treatises, the last of which contains a general outline of the whole work.

The interest attaching to this production, as the earliest Encyclopædia deserving the name, reflecting, as it does, the state of science both of the East and West at the end of the first thousand years after the introduction of Christianity, is so great, that we append a sketch of the contents and method.

The first 13 treatises, belonging to what may be called the mathematico-philosophical division, treat of Arithmetic, Geometry, Astronomy, Geography, Music, followed by psychological and ethical reflections. This part concludes with introductions to Philosophy and Logic. Throughout, the authors only treat of the theoretical part of their subject, without entering into further details as to their practical side, or teaching them systematically one by one.

From these preliminaries, the work proceeds to its second part, the physical division, which comprises the whole cosmos in its special phenomena, and the laws that govern them: heaven and earth, the three natural kingdoms, the mysterious union of body and soul, how the latter pervades the former, and communicates itself to all its parts; the changes of life and death, joy and mourning, the senses, and all that is perceptible through them—all the great questions, in fact, which most vitally engage man's attention in this world of growth and decay. An attempt is made to ascertain how far human understanding can penetrate these dim regions of speculation and metaphysics, and even the languages and their original elements are drawn into the circle of these investigations, and subjected to philosophical scrutiny.

The third division treats of the origins of mental activity. Heterogeneous though some of its elements be, it yet keeps its subject sufficiently in view throughout. The elements of mental activity are investigated first according to Pythagoras, then according to the Brethren themselves. Next comes man both as microcosm and macrocosm. The revolutions of the heavenly bodies, love, resurrection, the world to come, motion, cause and effect, dogmas and customs are then treated of; each and all contributing their share to the aimed-at outward union between reason and faith.

The fourth division borders very closely on the supranaturalistic and purely speculative. At the same time, it touches vital doctrines of Islam, and treats them in an abstract and very free manner. How the knowledge of God is gained; the life of the soul after death; the relation of the Brethren

towards each other; the essence of the true faith; the divine law; prophecy; and the relation of religion generally to the peculiar phase of it as adopted by the lodge; and a number of similar points are taken up.

So far, in the most general outlines, those fifty-one treatises, which, though they be neither strictly systematically arranged nor methodised, nor free from repetitions, and by no means so instructive in detail as the enumeration of the contents would lead to believe, yet belong to the most comprehensive and creditable efforts of the human mind.

A small specimen of the manner and method of these treatises, taken from the chapter (20) on Plants may not be unacceptable:

'Know that the plants are only perceptible as the visible, palpable phenomena, but that their artistic working within is secret, invisible, and hidden before the eye. It is what we call the part-souls, what the philosophers call the natural powers, what religion calls angels, or divine hosts commissioned with the calling into being and development of the plants and creatures, with the creation of the stones, &c. The terms differ, but the sense and meaning is identical. Philosophers trace these things to the Powers of Nature; the religious Law to the Angels, but not directly to the Blessed and Exalted God. For the Blessed God is too exalted to form a natural body Himself—to move and to act bodily, just as kings, generals, and high dignitaries are too high to execute any work themselves, though they are considered their authors, through having ordered and willed them. If, e.g., you hear it said that Alexander built Alexandria, you must not, of course, fancy that he himself bodily did build the city—he ordered it to be built. Thus, the works of God's servants are traced back to the Exalted God, even as the Koran says: "It is not you who have killed them, but God."

One of the most attractive portions of the work, and the one which alone has been repeatedly edited and translated into many languages (not into English), is the so-called 'Contest between Man and Animal,' which forms a part of the twenty-first treatise. In this one place alone, man and animals are introduced speaking; in all other portions, rhetoric, ornamented by allegories and metaphors, mostly well chosen and artistically wrought, forms the ordinary style. These dissertations may not have fulfilled their purpose any more than did the whole lodge; but they will be all the better appreciated when that darkest period of Mohammedan history, the 10th c., is taken into consideration. Hypocrisy stood for piety at the courts of the many emirs, low cunning for wisdom, the vilest adulation for fidelity, and oppression for justice. No wonder this manly and scientific protest was not received very favourably by so corrupt a generation. Besides which, the want of strict logical arrangement—a circumstance owing probably to the voluntary suppression of the intermediate portion—and the vagueness in which many of the most important points are treated, made even the few independent and faithful minds fail to appreciate it. The chief cause of the discontent which they excited among the contemporaries lay in their conciliatory tendencies. Theology pure and simple would not hear of philosophy. Religion, the orthodox champion said, was a revelation—divinely given, not to be understood even by human intelligence; philosophy, on the other hand, was a vain thing, treating of human things and other futile subjects. The philosophers, though they dared not be quite so outspoken on theology, felt no less keenly that there

was no compromise possible under these circumstances, even if they had not repudiated any notion of being 'reconciled.'

We have treated this subject somewhat more fully than usual, both on account of its deep intrinsic interest, as forming the most striking refutation of the commonplace notion that the religion of Mohammed was a stationary, hard, fanatical, and dotard creed, never questioned or reasoned upon by the Faithful; and further, because little or no information on the subject is generally accessible. The work itself has, as we have said, with the exception of the one fairy-tale fragment, never been edited; and there are, even among the authorities on Mohammedan matters, but three or four who have paid special attention to this important subject, and what fragmentary information we possess lies scattered in Oriental 'Transactions,' in notes, and in prefaces.—See Sprenger, in *Asiatic Journal of Bengal*; Flügel, in *Deutsche Morgenl. Zeitschrift*; De Sacy, *Notices et Extraits*; Dieterici, *Menack und Thier*; Nauwerck; &c.

SIR-I-PUL, a town of Bokhara, Turkestan, 45 miles south-west from Balkh, in lat. 36° 21' N., and long. 66° 29' E., on a river which loses itself without reaching the Jihoon. It is the capital of an Uzbek chief. Pop. 18,000.

SLEAFORD, a town of Lincolnshire, England, on the right bank of the Slea, a branch of the Witham, 17 miles south-south-east from Lincoln, and 52 feet above the level of the sea. It is a well-built and well-paved town, and has a fine church, built in the 13th century. Pop. (1861) 3745.

SMITH, GOLDWIN, the son of a Berkshire physician, was born at Reading in 1823. He received his education at Eton, from whence he proceeded to Oxford, and matriculated at Christ's Church, but was soon afterwards elected to a Demyship at Magdalen. His undergraduate career was one of unusual brilliancy, only equalled, indeed, by Sir Roundell Palmer and Professor Conington. He gained both University Scholarships, the Latin Verse, and the two Prize Essays, and was placed in the first class in 1845. In 1847, he was elected Fellow of University College, where he officiated for a time as tutor. In the same year he was called to the bar at Lincoln's Inn. The ministry of the day availed themselves of Mr S.'s services in carrying out their plans of university reform. He was nominated Assistant-secretary to the first, and Secretary to the second Oxford Commission, by which the somewhat antiquated statutes of the university were reconstructed, and the rich endowments of the colleges opened to public competition. Mr S. was also a member of the Popular Education Commission appointed in June 1858. The chair of Modern History having been vacated about this time by the resignation of Professor Vaughan, was offered by Lord Derby to Mr S., as the only man possessing claims equal, if not superior, to those of Froude the historian. He accepted the offer (April 9, 1858), and discharged his professional duties with zeal and efficiency until his resignation in 1866. Goldwin S. has long been known in the English press as a reviewer and publicist of the highest class, and has of late years completely identified himself with the more advanced school of reformers. During the American war, he was an earnest defender of Federal interests, and combated with success, in the *Daily News* and elsewhere, the singular theories of the rights of slavery and the duties of neutrals, which were then somewhat fashionable. He was also active in denouncing the Jamaica massacres, and in advocating an extended measure of reform. His lectures on 'Three English

Statesmen,' delivered at some of the chief towns in the north, called forth the remark from Mr Diarabel, that he was a 'wild man of the cloister, going about the country maligning men and things.' Mr S.'s writings are characterised by great extent and accuracy of information, by a style singularly vigorous and condensed, and by great powers of sarcasm. Among his principal publications may be enumerated: *Irish History and Character*; *Two Lectures on the Study of History, with a Supplementary Lecture on the Doctrine of Historical Progress*; *The Empire*, a reprint from the *Daily News* of 1862—1863; *England and America*, a lecture delivered before the Boston Fraternity, and reprinted from the *Atlantic Monthly*; *A Plea for the Abolition of Tests at Oxford*; *Rational Religion and the Objections of the Bampton Lecture* in 1858 (Professor Mansel's); several pamphlets on the American question, contributions to *Oxford Essays, &c.* Professor S. is also the author of some of the most admired compositions in the *Anthologia Ozoniensis*.

SNOW-BIRD (*Junco* or *Fringilla hyemalis*), a North American bird of the Finch family (*Fringillidae*), common from Louisiana to the Fur Countries, in all the eastern parts of North America. The wings are rather short, the tail slightly notched. The whole length is rather more than six inches; the upper parts are lead-colour, the lower parts white, the two outer tail-feathers white, the next white margined with black. This bird migrates northwards early in spring, and southwards late in autumn. It is often to be seen in small flocks, visiting barn-yards, and hopping about with the domestic poultry. In cold weather, it retires to holes in haystacks. Its song is sweet. From its frequent familiar approach to human habitations, the S. is regarded with favour throughout great part of North America, as the Redbreast is in Britain. In the south, however, it is often brought to market, its flesh being very pleasant. In the western parts of North America, another but very similar species, the OREGON SNOW-FINCH (*F. Oregona*), takes the place of this.

SOMBRERE'TÉ, a town of Mexico, in the state of Zacatecas, and 90 miles north-west from Zacatecas, in a mountainous district celebrated for its rich silver mines, from which S. derives all its importance. Pop. 14,000.

SOO-CHOW, or **SU-TCHOU**, or **SOO-CHOW-FOU** (*fo* merely signifying city), a large city of China, in the province of Kiang-su, 60 miles west-north-west from Shanghai. It stands near the Grand Canal which connects Hang-chow with Nanking and Peking, but its port is Shanghai, with which also it has water-communication. It is about ten miles in circumference, and is enclosed by fortifications, outside of which are four very large suburbs. The country around S. is level, and remarkable for its fertility, so that the Chinese speak of it as a terrestrial paradise. The city has silk manufactures, printing establishments, and a large trade in books. In 1857, S. was captured and sacked by the Taepings. In 1863, it was invested by the Imperialists, under a British officer, and the rebel chiefs having surrendered, were treacherously beheaded by the governor of the province.

SPANISH MAIN (i. e., *main-land*), a name generally given during the 16th c. and the earlier part of the 18th to the north-east coast of South America, from the Orinoco to the Isthmus of Darien. The name occurs very frequently in connection with the history and exploits of Buccaneers (q. v.).

SPEKE, JOHN HANNING, an African traveller, was born near Bideford, Devonshire, in May 1827,

and was the son of Mr W. Speke, the representative of an old Somersetshire family. He was educated at the Barnstaple grammar-school, and at the age of 17 went to India. He entered the native Bengal infantry as a cadet, and saw much service during the war in the Punjab. A keen sportsman, with a taste for natural history, he employed his rifle with success in collecting for the museums specimens of the rarer mammals and birds of India, and with this view he undertook several exploratory trips into the Himalaya. It was while so employed that he first conceived the idea of becoming an African traveller. The English government had resolved, in 1854, to despatch an expedition from Aden into the neighbouring region of Africa, under the command of Captain Burton (q. v. in SUPPLEMENT). S., then a lieutenant in the Indian army, reached Aden at this time, on leave of absence, and resolved to join Burton and his companions, Lieutenants Heme and Stroyan. Burton went to Harar; and S. was detached to visit the Dalbahantas, the most warlike of the Somaui tribes. On the return of the travellers to their starting-point on the coast, they were attacked by 150 men. Stroyan was killed, and S. made a narrow escape with 11 wounds. The attention of the Geographical Society of London had now been called to the subject of the great lakes of tropical Africa; and in June 1857, they despatched Burton and Speke. These travellers entered the country from Zanguebar, as the German missionaries Krapf and Kebmann had done in 1847, and discovered the great lake Tanganyika. The details of their discoveries till they reached Gondokoro, in March 1863, are given in the article NILE. S. and Grant had passed through the very heart of what remained of the *terra incognita* of Eastern Africa. On their return to England, they met with an enthusiastic reception, to which they were well entitled, as two of the most daring and successful of modern explorers; although, perhaps, some of S.'s most enthusiastic friends have gone too far in claiming for him a place above other travellers as 'the discoverer' of the sources of the Nile. On the 15th September 1864, S. was killed by a gun-accident while out shooting in the neighbourhood of Bath, to which he had come to be present at a meeting of the British Association.—S. is the author of a *Journal of the Discovery of the Sources of the Nile, and What led to the Discovery of the Source of the Nile*.

SPENCER, HERBERT, an English author, born in Derby in 1820. He was educated by his father, W. G. Spencer, a teacher, chiefly of mathematics, and his uncle, the Rev. Thomas Spencer, a clergyman of the established church, well known for his liberal opinions on political and ecclesiastical questions. At the age of seventeen, he became a civil engineer; but after about eight years, abandoned the profession, in consequence of the large influx of young men brought into it during the railway mania, and the consequent undue competition. During the eight years of his engineering life, he contributed various papers to the *Civil Engineer's and Architect's Journal*. His first productions in general literature were in the shape of a series of letters on the 'Proper Sphere of Government,' published in the *Nonconformist* newspaper in 1842, which were some time after reprinted as a pamphlet. From the close of 1848 to the middle of 1853, he was engaged on the *Economist*, then edited by the late James Wilson, M.P.; and during this time he published his first considerable work, *Social Statics*. Shortly afterwards, he began to write for the quarterly reviews, most of his articles appearing in the *Westminster*, and others in the *North British, British Quarterly, Edinburgh, Medico-chirurgical,*

&c. In 1855, appeared his *Principles of Psychology*. In 1860, he commenced the undertaking on which he is at present engaged—a connected series of philosophical works, designed to unfold in their natural order the principles of biology, psychology, sociology, and morality; the series being initiated by a volume entitled *First Principles*. Three volumes of the series have now been completed.

Mr S. displays great philosophical originality. In particular, he has carried out into systematic detail the theory of Evolution or Development, agreeing in the main with Mr Darwin.

SPERMATOOA (derived from Gr. *sperma*, seed, and *zoa*, living creatures) is the term given to the true fertilising agents occurring in the male generative organs. They appear to be formed from the epithelial lining of the tortuous seminal tubes, of which the organ known as the *testis* is essentially composed. At the period of puberty in man, and at certain periods annually in other animals, the seminal tubes are seen to be filled with cells, from which the spermatozoa are developed. Without describing the various changes that ensue, we may observe, that the spermatozoa are finally set free by the bursting of the cell-walls, and arrange themselves in parcels, symmetrically placed, with the so-called heads in one direction, and the tails in the opposite direction. In the human subject, the spermatozoa may be described as clear, hyaloid bodies, each of which consists of a dilated portion, the head or body, from which a long tail, or filament, issues. The head is flattened from side to side, and of a conical form, the pointed extremity being anterior. The length of the spermatozoa is about $\frac{1}{175}$ th of an inch. The spermatozoa of different animals vary extremely in size and form; and for a detailed account of these bodies, in different classes of animals, we must refer to the article 'Semen,' in the *Cyclopædia of Anatomy and Physiology*. It was formerly supposed that spermatozoa were independent organisms (like the infusoria, for example), but it is now known that they must be regarded as epithelial cells (or perhaps nuclei), modified in structure, and endowed with special properties. That the integrity of the spermatozoa is essential for the process of impregnation, is a fact that cannot be called in question; but of the nature of the force which they communicate to the ova, we know nothing.

SPHYGMOGRAPH, an instrument by which we ascertain, and permanently record, the form, force, and frequency of the pulse-beat, and the changes which that beat undergoes in certain morbid states. This instrument consists of two essential parts: (1) Of two levers, one of which is so delicately adjusted on the vessel the pulsation of which it is desired to examine, that on each expansion of the vessel the lever undergoes a corresponding slight elevation: this lever communicates by a perpendicular arm with a second, to which it transmits the impulse received from the vessel; the extremity of this second lever is armed with a pen-point, which records the movements thus indicated on a movable plate, controlled by the second part of the instrument. (2) The second portion consists of a plate, moved by watch-work, and bearing a strip of paper on which the *sphygmographic* tracery is formed.

Mode in which the Tracery is formed.—As the pulse transmits through the levers a vertical movement to the pen-point, and the plate, on which the tracery is formed, is moved steadily across the pen-point, an undulating line (fig. 1) is the result: the *height* of the elevations indicating the strength of the pulse; and the *number* of the elevations delineated in the time the pen takes to travel, its frequency.

Figs. 1, 2, and 3 are fac-similes of sphygmographic tracings: of these, fig. 1 is the tracing presented by a natural pulse; figs. 2 and 3 are morbid. The latter are excellent examples of the tracings produced by

Fig. 1.

the pulse at the wrist in two common forms of cardiac disease, and exhibit the manner in which the tracing is modified in diseased states of the circulatory system. Fig. 2 represents the pulse of a patient suffering from an incompetent state of the valves guarding the orifice of the aorta, the great vessel conveying blood from the heart. The blood, in such a case, when propelled into the aorta, distends it, and communicates a pulse throughout

Fig. 2.

the arterial system. When the vessel again contracts, regurgitation takes place into the cavity of the heart, as the valves, which should prevent this regurgitation, and maintain the arterial tension, are unable to perform their function. The pulse-beat is accordingly abrupt, and of short duration, and the sphygmographic tracing presents a series of abrupt elevations and depressions. Fig. 3 represents the pulse met with in a different form of

Fig. 3.

cardiac disease, in which the valves are so affected as to obstruct the passage of the blood into the circulation: the effect of this on the pulse is to render its beats weakly marked and irregular; and in the sphygmographic tracing, the elevations are diminished in height and regularity. The pulse, in extreme forms of this lesion, is represented in sphygmographic tracing by a slightly waving line.

SPITHEAD FORTS. The troubled state of European politics which gave rise in 1859 to the Volunteer movement, led also to the recommendation of an extensive plan of defences for the arsenals and coast. A Board of Commissioners drew up a scheme for these defences, to cost about £5,000,000, of which a sum of £2,000,000 was for Portsmouth, Spithead, and the neighbouring coast. At present, the entrance to the important arsenal and dockyard at Portsmouth is defended by Fort Monckton on the Gosport side, Southsea Castle on the opposite side, Cumberland Fort at the entrance to Langston Harbour, Lumps and Eastney Forts between the two last named, and some defensive lines between the island of Portsea and the mainland. £580,000 was voted in 1860 as a beginning, to increase the number and strength of these forts, to build detached forts on shoals in the sea between the mainland and the Isle of Wight, and to raise fortified lines on Portdown Hill (the principal work being Fort Southwick), wholly northward of Portsmouth Harbour. The works were commenced; but

the often-conflicting lessons furnished by the American war led to much delay and endless variations of plan.

The National Defence Commissioners had proposed five advanced forts on the shoals known as Horse Sand, Noman or No Man's Land Shoal, Sturbridge Shoal, Spit Point, and a point intervening between Horse Sand and Portsea Island. But after much discussion and numerous alterations of plan, it was only in 1864 that it was determined to proceed with the foundations at least of two—the Horse and the Noman forts. The foundation of each fort consists of rings of stone-work, laid on the levelled bed of the shoal, tapering a little upwards from a width of 54 feet to one of 43 feet; the outer diameter of the ring gradually lessening from 231 to 213 feet. From 20 to 15 feet of submarine masonry is required. Outside the rings of stone are layers of rubble, to protect the stone-work from the action of tidal rush. In the same year, 1864, which placed in abeyance all the Spithead forts except the Horse and the Noman, the construction of a small fort was begun beyond Spithead itself, but near the entrance to Brading Harbour in the Isle of Wight; an oval fort of 120 feet by 109, built of granite within a ring of caissons sunk in the sand.

All this time the government had not determined which of three modes to adopt for constructing the forts, the foundations of which had thus been commenced—whether to form them entirely of iron; or of granite faced with iron, like the forts constructed by the Russians at Cronstadt; or simply of granite, leaving the facing for after-consideration. The plan most in favour with the government in 1866 was to erect on each of the foundations at Spithead a revolving iron fort or tower of enormous magnitude and strength.

Circumstances in 1867 induced the government again to pause. Experiments on the Rodman 15-inch and 20-inch guns led some engineers to believe that no iron casing for forts could resist shot of 500 lbs. to 1100 lbs. from such ordnance; while the rolling (in September) of an armour-plate 15 inches thick (thicker than any before produced; for which see ARMOUR-PLATES in SUPPLEMENT) by Sir John Brown & Co. of Sheffield, revived the hopes of those who believe that armour will eventually vanquish guns. The year 1868 began with the Spithead forts still waiting for a decision on these important matters; the foundations being in, but the forts themselves not built.

STANFIELD, CLARKSON, a distinguished painter, was born of Irish parents, in the town of Sunderland, about the year 1793. At an early period of his life, he went to sea, and made frequent long voyages, among which was that to China. In the China seas, he passed some years of his life, and served for a time in the same ship with Douglas Jerrold; S. in the capacity of a common sailor, and Jerrold as a midshipman. While thus engaged, S. exhibited considerable talent both in painting and drawing. The first person of public note, however, to observe S.'s genius as a painter was the celebrated Captain Marryat, who met with him in the Mediterranean, serving in a king's ship as captain's clerk. S. and Marryat afterwards became intimate; and in 1840 the novelist employed the painter, then become famous, to illustrate his *Poor Jack*. S. left the navy, in consequence of an injury to his feet, through a fall from the fore-topgallant mast-head of his ship. He then took to scene-painting as a means of earning his bread. His first efforts in this direction were made in the Old Royalty Theatre, Wells Street, Wellclose Square, in the east end of London, about the year 1818. He was afterwards

employed at Drury Lane Theatre, and here it is said that he produced some of his most extraordinary effects. He carried on this occupation until the year 1827, when he finally abandoned it, except on rare occasions. S., while painting for the theatres, had by no means neglected easel-painting. The first picture by him that attracted any considerable notice was 'Market-boats on the Scheldt,' exhibited at the British Institution in 1826. The picturesque grouping, variety of figures, and gay costumes were much admired. His 'Wreckers off Fort Rouge, Calais,' exhibited in the following year, also at the British Institution, was even more successful. In 1828, he obtained from the British Institution a prize of fifty guineas for another of his pictures. In 1830, S. made his first excursion on the continent, and in the same year exhibited at the Academy his 'Mount St Michael, Cornwall,' which placed him at once in the foremost rank as a marine painter. In 1823, S., in conjunction with David Roberts and others, founded the Society of British Artists. His election to the Academy as Associate took place in 1832; and in 1835 he was chosen R.A., in conjunction with Sir William Allan. In 1833, S. exhibited at the Academy the first of a series of pictures of Italian scenery, painted for the Marquis of Lansdowne for the banqueting-room at Bowater. In 1834, he commenced a similar series for the Duke of Sutherland. In 1836, he exhibited 'The Battle of Trafalgar,' painted for the Senior United Service Club; and in 1841, his celebrated 'Castello d'Ischia,' engraved by the Art-union in 1844. In 1843, he sent to the Academy 'Mazerbo and Lucello, Gulf of Venice,' said to be one of the finest landscapes he ever painted. 'A Skirmish off Heligoland' (1867) was S.'s last contribution to the exhibitions of the Academy, of which he was so distinguished a member. His great merit lies in the skillful combination of land and sea in the same view. Man and the works of man are not disdained by him in his portraiture of nature, and there is frequently a poetic feeling of the highest order in some of his conceptions, as in his pictures of 'The Abandoned,' and 'The Wreck of a Dutch East Indiaman.' S. died on the 18th of May 1867.

STA'TEN ISLAND, an island off the south-east point of Tierra del Fuego, from which it is separated by the Strait of Le Maire. It is about 45 miles in length from east to west, and about 10 miles at its greatest breadth, its shores much indented. Its eastern extremity is Cape St John, in lat. 54° 42' S., and long. 63° 43' W. The surface is mountainous, descending to the sea in steep slopes and precipices; its general character similar to that of Tierra del Fuego.

STAVA'NGER, a seaport town of the west coast of Norway, in the stift of Christiansand, 35 miles north-west from the Naze, and 100 miles south from Bergen, on the west side of a wide and sheltered bay of the Bukke-fiord. It is a very ancient town, with a very fine old Gothic cathedral, called St Swithin's. S. has cloth-manufactories and distilleries. Ship-building is carried on. There is a considerable export trade in timber, oak-bark, lobsters, herring, and stock-fish. Pop. 12,000.

STAVESACRE (*Delphinium staphisagria*), a species of Larkspur (q. v.), a native of the south of Europe. The seeds have been used in medicine from ancient times. They are too violently emetic and cathartic to be safely employed; but in powder they are applied to cutaneous eruptions, and are used for killing lice. Their properties depend upon an alkaloid, *Delphinia* (C₂₇H₁₉NO₇), which is now

STEAM-CARRIAGE—STEEL

used in medicine, instead of the seeds, chiefly in rheumatism and neuralgia.

STEAM-CARRIAGE. In November 1867, Mr R. W. Thomson, C.E., of Edinburgh, invented and patented a new kind of wheel for traction-engines on common roads. The tires are made of a band of vulcanised india-rubber about 12 inches wide and 5 inches thick. Incredible as it may appear, this soft and elastic material carries the great weight of the traction-engine without sustaining any injury even when running over broken stones. Recent trials have proved that Mr Thomson's patent wheels enable the traction-engine to run over soft

and bad roads with a facility not attainable when ordinary wheels are used. The *bite* is also so perfect that no tendency to slip is shewn on the worst of roads. The wheels hitherto in use required projections of some kind on the face of the tires to give the requisite bite. Those projections necessarily destroy the roads. Mr Thomson's wheels do not injure the roads in the slightest degree. They are not crushed under the wheels, nor is the machinery injured by jolting. The carriage rolls along as easily as if it were aloft.

STEAM-CRANE. The application of steam to the working of cranes was an obvious one, and is

Steam-crane.

now universal where much crane-work has to be done. When a number of cranes are at work near one another, they are all supplied by one steam-boiler, the small cylinder and piston attached to each crane having its own steam-pipe. Steam-cranes and steam-winchies are in universal use in all large steamboats, as many as seven or eight being fitted up on board of one ship. The portable balance steam-crane was invented by Mr R. W. Thomson, C.E., in 1856, since which date many hundreds have been made. They are now in use in all parts of the country wherever heavy weights are to be raised. The figure represents a crane, fitted with the differential rotary engine and boiler described in the article **STEAM-ENGINE**. The portable crane can be constructed to work with the ordinary kind of engine and boiler. The essential feature of the portable balance steam-crane is the use of the boiler as the counterpoise for the weight to be lifted. The boiler, engine, and man who works the machine all swing round with the crane. By raising or depressing the handle A, the whole

structure, carrying a heavy burden at the end of the jib, can be rapidly slewed round in either direction by the action of the steam-engine. By a simple addition to the mechanism, the crane can be made to propel itself along a line of rails.

STEEL, JOHN, R.S.A., an eminent Scottish sculptor, the son of a carver and gilder in Edinburgh, was born at Aberdeen in 1804. He received his education as an artist at the Edinburgh Academy, and afterwards at Rome. On returning thence in 1830, he executed a colossal group of 'Alexander and Bucephalus,' which was instantly recognised as a work of great merit. The promise of this early work he has since amply fulfilled; and is now admitted to stand in the front rank of his profession. His chief works are to be seen in Edinburgh. Of such are the colossal figure of the Queen crowning the front of the Royal Institution; which procured him the honorary appointment of Sculptor to Her Majesty in Scotland; the statue of Scott in the interior of the Scott Monument, a commission which was won in competition; the

equestrian statue of the Duke of Wellington, erected in 1852; and more lately, the two fine works representing Professor Wilson and Allan Ramsay.

STOCK-BROKER, or SHARE-BROKER, a person employed in buying and selling stock in the public funds, or shares in the capital of a joint-stock company. A sale or purchase of stock, if not transacted directly between seller and purchaser, must be accomplished through means of a licensed stock-broker. Stock-brokers are subject to the restrictions of the statute known as Sir John Barnard's Act (7 Geo. II. c. 8, rendered perpetual by 10 Geo. II. c. 8). This act requires every stock-broker to enter all his contracts day by day in a book to be kept for the purpose, under a penalty of £50 for every omission. Contracts in which there is no *bond fide* sale of stock, entered into by way of speculating on the fluctuations of the market, are declared void, and those who engage in them are liable to a penalty of £500. A similar penalty attaches to any agreement to sell stock of which one is not in possession. The charge for brokerage is 2s. 6d. on all public funds except Exchequer bills and India bonds: on these it is 1s. per cent.

SUEZ CANAL. In the former article on this subject, the nature of the scheme was briefly described, and illustrated by a small map; and the progress of the works noticed down to the year 1865. In this place, some of the features will receive a little further explanation, with reference to the progress attained down to the end of 1867.

The Port Said Entrance.—Port Said or Saïd, a town now containing 10,000 inhabitants, had no existence in 1862. Port Said is the *dépot* of the Company, the metropolis of vast bodies of labourers and other persons employed on the works of the canal. As the Mediterranean Sea is very shallow near this point, an artificial deep channel has had to be made, bounded east and west by piers stretching far out into the sea. Stone for these piers was, in the first instance, brought from a long distance; but artificial stone is now made on the spot. It is made of two parts of sand and one part of hydraulic lime ground into a paste, and poured into wooden boxes or moulds. When the mixture is solidified, the mould-boards are removed, and the solid blocks of artificial stone are left from three to six months in the open air to dry and harden. The blocks contain 10 cubic metres each, weigh 20 tons, and are made at a contract price of 42 francs per *mètre cube*. The western pier, in October 1867, was finished to a length of 2700 yards, and the eastern nearly as much: they are 1500 yards apart at the shore, but gradually approach towards each other at the outer ends. The western pier is being continued in an arc of 1100 yards' extent, so as, with the eastern pier, to shelter the harbour from all winds. A portion of the space between the piers is being dredged to a depth of 26 feet. Within this outer harbour is an inner port, 870 yards by 500, 14 feet deep, but being gradually deepened to 26 feet.

From Port Said to Tensah Lake.—From Port Said, the canal crosses about 20 miles of Menzaleh Lake—a salt-water shallow, closely resembling the lagoons of Venice, having from 1 to 10 feet depth of water. The canal through this lagoon is 112 yards wide at the surface, 26 yards at the bottom, and 26 feet deep. An artificial bank rises 15 feet on each side of this channel. Beyond Menzaleh Lake, heavier works begin. The distance thence to Abu Ballah Lake is 11 miles, with a height of ground above the level of the sea varying from 15 to 30 feet. Crossing the last-named lake, there is another land distance of 11 miles to Tensah Lake,

cutting through ground to a depth varying from 30 to 70 or 80 feet; and then 3 miles further across this little lake itself. Ismailia, on Tensah Lake, is regarded as the central point of the canal. It is growing up from an Arab village to a French town, with the houses of engineers and managers, an hotel and shops—the tents of the Arab labourers forming a distinct town at a little distance. In October 1867, the whole of the works from Port Said to Ismailia were in a very advanced state.

The Fresh-water Canal.—This extends from the Nile to Tensah Lake, and was constructed purposely to supply with water the population accumulating at various points on the line of the canal; but it is also used temporarily for navigation. This fresh-water or 'sweet-water' canal comprises three portions or sections: (1) from the Nile east or north-east to Ismailia, on Tensah Lake; (2) from Ismailia, nearly south to Suez, on the western side of the great ship or maritime canal; (3) from Ismailia nearly north to Port Said, also on the west side of the ship canal. The first and second of these sections are really canals, large enough to accommodate small steamer and barge traffic; but the third section consists simply of a large iron pipe, through which the water is conveyed to the several stations. Plugs are inserted in the pipe wherever needed, to allow water to be drawn off for everyday wants. All the three sections of this fresh-water canal were finished and in operation long since.

From Tensah Lake to Suez.—Southward of the central point at Ismailia, there is a space of 8 miles from Tensah Lake to the commencement of the Bitter Lakes, which has had to be dug to a depth varying from 30 to 62 feet, according to the undulations of the surface. In these deep cuttings, owing to the great width of the canal, the quantity of sand (for it is nearly all sand, though sometimes agglomerated with clay) to be dug out is enormous, requiring the constant labour of a large number of powerful dredging machines and elevators. At El Guisr, or Girsch, occurs the deepest cutting in the whole line, no less than 85 feet below the surface; at the water-level it is 112 yards wide, at the summit-level 173 yards, from which the vastness of the gap may be estimated. In October 1867, two-thirds of this cutting were finished above the water-level; but below that level, only the depth and width for a small temporary canal were finished. In passing through the Bitter Lakes, the works are comparatively embanking rather than excavating, seeing that the bottom of this region is only two or three yards above the intended bottom of the great canal. From the southern end of the Bitter Lakes to Suez, a distance of about 13 miles, there is another series of heavy cuttings, varying from 30 to 56 feet in depth; of which the portion remaining to be finished is very great.

Vague and hasty notices in the newspapers lead occasionally to a belief that trade has commenced on this great ship canal; but this is far from being the case. All the notices refer either to the fresh-water canal, or to a narrow belt of the great canal. In October 1867, salt-water extended from Port Said to El Toussoun or Tussum, a little southward of Tensah Lake; but from thence to Suez there was only the fresh-water channel available. Vessels drawing from 8 to 9 feet water could reach Tussum from Port Said, and smaller vessels took the fresh-water route onward to Suez. Since that date, large quantities of stores have been conveyed along this temporary channel by lighters and steam-tugs, for the British expedition to Abyssinia. It was estimated that only one-third of the earthwork on the great canal was finished at that date. As a commercial

speculation, apart from political motives, it is almost universally believed in England that the S. C. will not pay. The yearly cost of maintenance will be heavy. Already there is an accumulation of sand on the sea-frontage of Said, entirely caused in two years by the combined action of the eastern pier or jetty and a western current; and time only will shew whether the loose sand of the shore and of the isthmus generally can be effectually mastered. It is a grand work, and *deserves* to succeed.

SULPHUROUS ACID has during the last two years become one of the most popular articles in our Pharmacopœia. This sudden popularity is mainly due to the researches of a Scottish provincial physician, Dr Dewar of Kirkcaldy, who, from beginning his experiments on cattle during the period of the late pestilence, extended them to other animals and to man, and has finally obtained a series of results, which, if they stand the test of experience, will insure for him a place in any future history of medicine. There is, of course, nothing new in applying sulphur-fumes—which in reality are composed of sulphurous acid gas—as a disinfectant. The classical scholar will recollect that Ulysses employed them to remove the unpleasant smell arising from the dead bodies of Penelope's murdered lovers. 'Bring brimstone, the relief of evils,' he exclaims, 'and bring me fire that I may sulphurise the house.'—Hom. *Od.* xx. 481, 482. It is also recorded by Ovid (*Fast.* iv. 735) and other writers that the shepherds of Italy yearly purified their flocks and herds with 'the blue smoke of burning sulphur.' Professor Graham's remark, that of gaseous disinfectants, sulphurous acid (obtained by burning sulphur) is preferable, on theoretical grounds, to chlorine, and that no agent checks so effectually the first development of animal and vegetable life, may be said to contain all that was known with regard to the medicinal value of this gas, till Dr Dewar began his investigations. In his experiments in connection with the cattle-plague, he found that the most safe and convenient apparatus consists of a chafin two-thirds full of red cinders, a crucible inserted in the cinders, and a piece of sulphur-stick. A piece of sulphur as large as a man's thumb will burn for nearly twenty minutes, and will suffice for a cow-house containing six animals; and it appears undoubted that if there be due ventilation, this process may be performed four times a day for at least four months with positive advantage to the animals. When this system had been efficiently carried out—and it has been largely tried by his friends—no case of illness, not to say of death, occurred. In Mr Crookes's Report *On the Application of Disinfectants in arresting the Spread of the Cattle-plague*, that able chemist observed that 'the value of sulphurous acid in arresting the progress of the cattle-plague has been proved beyond a doubt by the experiments of Dr Dewar, and my own results entirely confirm his.' His experiments in relation to the cattle-plague led Dr Dewar to the further discovery of the value of sulphur fumigation in other departments of veterinary medicine. Peripneumonia, ringworm, mange, are amongst the diseases which rapidly disappear under its influence; and in the sudden undefined illnesses known in Scotland as 'drows' and 'towts,' to which most of our domestic animals are liable, sulphurous fumigation, if applied at the outset, rarely fails to cut short the attack.

In medical practice, there are three different forms, independently of the sulphites, in which sulphurous acid may be employed—viz (1) the sulphurous acid of the British Pharmacopœia, which contains 92 per cent. by weight, or about twenty times the volume of sulphurous acid gas

dissolved in water; (2) in the form of spray, which escapes from the preceding compound under the action of an apparatus called a Spray-producer; and (3) as a gas evolved by sprinkling at intervals small quantities of 'flowers of sulphur' on red-hot cinders placed on a common shovel, resting on a stool in the middle of the room. A mixture of equal parts of sulphurous acid and water is highly recommended by Dr Dewar as a healing agent in all cases of 'breaches of the skin,' as primary wounds, whether resulting from injuries or from surgical operations, in ulcers, burns, bed-sores, chapped hands, chilblains, saddle-sores (whether of man or beast), sore nipples, and in cases of bruises, such as black-eyes, &c. Moreover, in erysipelas, its soothing properties, if diluted with two or three parts of water, are very striking. According to Dr Dewar, the feverish irritability of young children is speedily relieved by dropping from time to time a few minims (5 to 30, according to age) of the acid on a few folds of muslin fastened on the breast: here, however, the action is not local, but is due to the evolution of the gas which is inhaled. Amongst the cases in which the acid is serviceable, when applied in the form of spray or inhaled as gas, are asthma, bronchitis, catarrh, croup, diphtheria, facial neuralgia, laryngeal affections, phthisis (at all events as a palliative), scarlatina, and typhoid. Dr Dewar ascribes the healing action of sulphurous acid to its power of destroying fungi. That the acid has this power, we freely admit, but we cannot so readily admit the correctness of his view that all the diseases in which he has found it serviceable (including piles and chilblains) are dependent on fungous growths. Dr Dewar reports a case of severe sciatica, in which immediate and perfect relief was afforded by the injection of an ounce of sulphurous acid in a breakfast-cupful of gruel into the rectum. There is one affection of this class, to which Dr Dewar does not refer, in which it has been prescribed with advantage—viz, the form of gastric disorder in which *Sarcina Ventriculi* (q. v.) occurs in the vomited matter, the dose being half a drachm, largely diluted with water.

None of the sulphites or hyposulphites have as yet been introduced into the Pharmacopœia. We notice them here because their action is supposed to depend upon the liberation of sulphurous or hyposulphurous acid when the salt comes in contact with the acid juices of the stomach. It is mainly to Dr Polli that we are indebted for the introduction of the sulphites and hyposulphites of the alkalies and alkaline earths (soda, potash, and magnesia) into medicine. From the year 1857 to the present time, he has devoted almost all his time to the study of these agents. His labours are briefly summed up as follows by Dr Sanson in an excellent Memoir on 'The Germs of Cholera, and the Means of their Destruction,' just published (January 22, 1868) in *The Medical Press and Circular*: 'It was found that animals could, without any apparent ill effects, swallow and absorb large doses of the sulphites. It was then observed that when the animals were killed, they long resisted the putrefactive process. Another series of experiments—and in this series 300 dogs were the basis of the deductions—shewed that the sulphites exerted a prophylactic and curative power when septic poisons were introduced into the economy. Then, as regards the human subject, it was found that the stomach would tolerate large doses of the sulphites of soda or magnesia. They were tried in the various eruptive fevers, intermittent, diphtheria, typhus, typhoid, cholera and choleraic diarrhoea, pyæmia, puerperal fever, dissection wounds, malarial infection, &c. The records of cases treated in this way shew an

extraordinary amount of success.' In a paper published by Dr Polli himself in *The British Medical Journal* for November 16, 1867, he states that since the promulgation, in 1861, of his views regarding the therapeutic value of the sulphites, no less than 153 papers on the subject have appeared; and with the exception of five or six containing certain criticisms on his labours, 'all the remainder confirm, in the strongest terms, by many hundreds of detailed observations, the value of these remedies.' A scruple of the salt dissolved in a wine-glassful of water flavoured with tincture of orange-peel, is the average dose, and it should be taken every four hours; and in some cases, as in typhoid, a grain of quinine may be advantageously added to each dose. M. de Ricci (*Dublin Quarterly Journal*, November 1866) prefers the sulphite of magnesia on the grounds, that it is less unpalatable, and contains a larger proportional quantity of acid than the soda salt. He predicts (and Dr Sanson and other physicians of repute agree with him) that eventually the treatment of zymotic diseases by the administration of the sulphites will be as fully recognised as that of ague by cinchona.

In consequence of the powerful antiseptic properties of sulphurous acid, either in the form of gas or gaseous solution in water, and of the sulphites, these substances have been employed for the purpose of preserving meat from putrefaction. A joint of meat or a fowl submitted to a daily sulphur fumigation, may be kept fit for use for many weeks. The bisulphite of lime has been found to be the most applicable of the various compounds of this class as a preservative; and Messrs Medlock and Bailey have patented a method of preserving meat by means of a preparation of this salt. In hot weather, a few drops of a strong solution of this salt will serve to keep fresh a pint of soup, jelly, milk, &c. Dr Dewar has patented a method of preserving meats by sulphurous acid, or some of its compounds; but the nature of his processes has not yet been made public.

SUMNER, CHARLES, American statesman, was born at Boston, Massachusetts, January 6, 1811. His father was a lawyer, and for many years sheriff of the county. He was educated at Harvard College, where he graduated in 1830; studied law at the Cambridge Law School; was admitted to the bar in 1834, and entered upon a large practice; edited the *American Jurist*; published three volumes of Sumner's *Reports of the Circuit Court of the United States*; gave lectures at the Law School, but declined a proffered professorship; and from 1837 to 1840, visited England and the continent of Europe. On his return, he edited *Vesey's Reports*, in 20 vols., and in 1845, made his debut in politics in a 4th of July oration, on the True Grandeur of Nations—an oration against war and the war with Mexico, pronounced by Mr Cobden the noblest contribution by any modern writer to the cause of peace. Identifying himself with the Free-soil party, he was, in 1850, chosen U. S. senator from Massachusetts, in place of Daniel Webster, where he opposed the Fugitive Slave Law, and declared 'freedom national—slavery sectional.' In 1856, he made a two days' speech on 'the Crime against Kansas,' some of which was of a violently personal character, in consequence of which he was attacked in the Senate Chamber, May 22, and severely beaten by Preston C. Brooks, and so severely injured that his labours were suspended for three or four years; during which he visited Europe for repose and health. Returning to the Senate, he supported the election of Mr Lincoln, urged upon him the proclamation of emancipation, and became the leader of the Senate, as chairman of the Committee on Foreign Relations,

where he continued after the war to sustain the extreme radical policy, in opposition to President Johnson and his cabinet. Of his published works are: *White Slavery in the Barbary States* (1853); *Orations and Speeches* (1850); *Recent Speeches and Addresses* (1856).

SUPPLE JACK, a name given in the southern parts of the United States of America to the *Berchemia volubilis*, a twining shrub of the natural order *Rhamnaceæ*, which is found as far north as Virginia. It has oval leaves, small flowers, and violet-coloured berries. It abounds in the Dismal Swamp and in similar situations, and ascends to the tops of the highest trees. The genus *Berchemia* contains a number of species of twining shrubs, natives of warm climates in different parts of the world.—The name S. J. is also given in the West Indies and tropical America to *Serjania* (or *Seriana*) *tritermata*, a shrub of the natural order *Sapindaceæ*, with a long, flexile, woody stem, which climbs to the tops of the highest trees, and is used for walking-sticks. It has poisonous properties, and is employed for stupefying fish.

SVENIGORO'DKA, a town of Russia, in the government of Kiev, 150 miles south from Kiev, on an affluent of the Southern Bug. Pop. (1863) 11,010.

SWAMMERDAM, JAN, a distinguished naturalist, was born at Amsterdam, 12th February 1637. S., almost from his boyhood, shewed the greatest eagerness in the study of natural history. Having entered upon the study of medicine, he particularly occupied himself with anatomy, and continued unremittingly to collect insects, to investigate their metamorphoses and habits, and, by the aid of the microscope, to examine their anatomic structure. He took his degree of Doctor of Physic at Leyden, in 1667, and entered upon the practice of his profession, which his bad health, however, soon compelled him to relinquish. He continued to be chiefly engrossed with anatomy and entomology. His treatise on Bees appeared in 1673; a treatise on Ephemera in 1675. It is impossible, however, for us to enumerate his many publications, all of which were first published in Dutch, and afterwards translated into Latin, and many of them into English, French, and German. S.'s discoveries were very numerous, both in human and comparative anatomy. His skill in using the microscope was very great, and his manipulation of the most minute subjects extremely dexterous. He succeeded in giving distinctness to the forms of very minute viscera, by inflating them with air; a method of his own invention. It is melancholy to add, that S., who had always displayed strong religious feelings, and expressed them in his writings, was at last carried away by the fanatical extravagances of Antoinette Bourignon (q. v.), began to think all his former pursuits sinful, and relinquished them for a visionary religious life of mere meditation and devotion. His health rapidly declined, and he died at Amsterdam, 17th February 1690. No man of his time contributed more than S. to the progress of natural history and physiology. He was the inventor of the method of making anatomical preparations by injecting the blood-vessels with wax, and also of the method of making dry preparations of the hollow organs, now generally employed.

SWATOW, or CHAU-CHOU, a seaport town on the coast of China, in the province of Quang-tung, 212 miles east-north-east from Canton. It is one of the ports which were opened to foreign trade by the treaty of Tien-tsin, and has a resident British consul. The trade is rapidly increasing. In 1860,

SYME—TECHNICAL EDUCATION.

the value of exports and imports together was 6,176,293 dollars; and in 1864, it was 13,369,499 dollars. Opium is the chief article of importation, next to which rank cotton and woollen goods, metals, and cotton-yarn. The chief exports are sugar, rice, tobacco, and paper. S. is pleasantly situated on a sheltered bay.

SYME, JAMES, was born in 1799, in the county of Fife, and received a thorough education in art and medicine, in the University of Edinburgh. In his 19th year he began his anatomical studies under Liston, who appointed him his demonstrator. From 1825 to 1832, he lectured on Surgery in the Edinburgh school, and, while generously refusing to lecture in opposition to his old master in the Edinburgh Infirmary, he established a hospital at his own expense, where he delivered a clinical course for four years. In 1831, appeared his well-known treatise on *The Excision of Diseased Joints*; and in 1832, his *Principles of Surgery*, which has since gone through many editions, and which has established his reputation as a teacher of the first rank. In 1833, he was elected to the chair of Surgery in the

university of Edinburgh, which he still holds with the highest distinction. In 1847, he gave up his Edinburgh chair to fill that vacated in London by the death of Liston; but collegiate misunderstandings induced him, after six months, to return to Edinburgh. As an operator, Mr S. has no superior; as a teacher, he has no equal. His innovations in the practice of his art are characterised by so much ingenuity, controlled by scientific caution, that they have been adopted by all really great surgeons. The best of his pupils, who are numerous, and scattered over every quarter of the globe, have been heard to declare that their soundest ideas in surgery are derived from Syme. Besides the works already named, he has written very valuable treatises on Diseases of the Rectum; on the Pathology and Practice of Surgery; On the Structure of the Urethra and *Fistula in Perineo*; On Incised Wounds; &c.

SZARVAS, a town of Hungary, in the county of Bekes, in a plain on the Körös, 22 miles north-east from Csongrad. It has a considerable trade in corn and cattle. Pop. 18,917.

T

AI-YUAN, a city of China, in the province of Shan-si, on the Fuen-ho, 250 miles south-west of Peking. It is said to be about ten miles in circumference, fortified and populous. Porcelain, iron wares, and carpets are manufactured.

TAVIRA, a seaport town of Portugal, in the province of Algarve, 20 miles north-east of Faro, pleasantly situated at the mouth of the Sequa. T. has decayed considerably since 1654, in which year, it is said, 40,000 people in the town and environs fell victims to the plague. Pop. (1863) 10,903.

TCHERKA'SI, a town of Russia, in the gov. of Kiev, 100 miles south-east of the town of Kiev, on the Dnieper. Pop. (1863) 20,387.

TECHNICAL EDUCATION (Gr. *techné*, art) means special instruction and training for the industrial arts. This subject has of late attained considerable importance, in consequence of comparisons drawn in the Paris Exhibition between the manufactures of several continental nations and those of Great Britain. Some persons maintain, that owing to the establishment of schools for special instruction in industrial arts and manufactures, our neighbours are making much more rapid progress than we are. Hence, it is assumed that the government should at once establish schools for the especial training of pupils intended for manufacturing pursuits.

The subject of technical training is not, however, a new one in Britain; it was seriously started by the Council of the Society of Arts in London in 1853, when a committee of that body was appointed to take into consideration, and to report how far and in what manner the Society of Arts could aid in the promotion of a more general and systematic cultivation of arts, manufactures, and commerce. This committee did their work very thoroughly, and collected an immense number of opinions and reports from influential merchants, manufacturers, and teachers—all of whom insisted upon the want

of this element in the education of the country. In June 1869, a minute was passed by the Committee of Council on Education, establishing a system of scientific instruction in the schools receiving government aid; and in consequence thereof, grants in aid of the salaries of competent teachers, and prizes to successful pupils, were guaranteed. The following were the subjects determined upon as necessary: 1. Practical and Descriptive Geometry, with Mechanical and Machine Drawing, and Building Construction. 2. Physics. 3. Chemistry. 4. Geology and Mineralogy (*applied to Mining*). 5. Natural History. Thus the government offered the means for scientific instruction to all classes, and also furnished the stimulus of prizes to persevering students; and already some very important results have been produced by this system, which has developed a large number of evening-classes, and has attracted very numerous pupils, both adult and juvenile, nearly all of whom belong to the artisan classes. The following table will at once shew this:

| | Number of Schools. | Number of Students. |
|-----------------|--------------------|---------------------|
| 1860, | 9 | 500 |
| 1862, | 70 | 1,330 |
| 1864, | 91 | 4,660 |
| 1866, | 153 | 6,535 |
| 1867, | 212 | 10,220 |

In the 212 schools, there are 560 classes for different subjects; and of the 10,220 students, 4520 came up for examination. This proves that we have a system already in good working-order, which only requires to be added to as necessity demands, in order to diffuse generally, amongst the classes most interested, a sound knowledge of elementary science. Besides the government plan of science-classes, there are many private establishments for a higher class of students, where technical subjects are well taught: foremost amongst these is the Training College at Chester, under the able superintendance of the Messrs Rigg, where every branch of mechanics is thoroughly taught in workshops on an extensive scale, in which the pupils can even

produce a steam-engine, and where also they learn carpentry and other useful arts. At this school, very many young men have been educated during the last twenty years. Very little has been done for technical education by the Mechanics' Institutions, which ought naturally to have striven more in this direction than any other. But there is one institution of this class which deserves especial mention, from its great and well-merited success, and for the benefits it has conferred upon a very large number of students, who would otherwise have had no opportunities of obtaining the sound instruction which has been given to its well-attended evening classes: we mean the Watt Institution and Edinburgh School of Arts, which was established in 1821, with the intention of affording instruction to mechanics in the sciences bearing on their occupations. The subjects taught in the various classes are, Mathematics, Natural Philosophy, Chemistry, Modelling, Arithmetic and Algebra, Drawing, English, French, and German; and for many years, the number of students has been between 700 and 800 annually. In this school, a small fee is required, 10s. admitting the student to the classes of Mathematics, Natural Philosophy, Chemistry, and English. It seems strange, and a matter also for regret, that so very useful a plan has not been adopted in other towns.

The technical schools of the continent have been called into existence by many circumstances which do not exist amongst ourselves, and which it is not desirable to enter into in this article; but much as they have been spoken of, they do not seem to have so large an attendance as might be supposed, and they are chiefly used by the upper classes. From a return, made in 1864, of the technical schools of Germany, Belgium, and France, the entire number of pupils in the polytechnic schools of all those countries was only 7151, of which 3000 were in Bavaria alone, where the want of gymnasia and the real-schools, so common in other parts of Germany, seems to drive students to the other class of schools.

From opinions lately collected, it is clear that on all sides it is felt desirable to increase our means of science-teaching in public and proprietary schools, and to endow chairs in our universities for teaching the higher branches of mechanics, mining, physics, practical chemistry, and the economic applications of raw products of the animal, vegetable, and mineral kingdoms.

Much information on this interesting subject may be obtained from the Reports of the Department of Science and Art; the *Journal of the Society of Arts*; and especially from the various papers of Dr Lyon Playfair, C.B., who has persistently kept the matter before the public ever since 1851, and the Report lately published by Mr Samuelson.

TEJUCIGALPA, a town of Honduras, Central America, is situated on a table-land 3428 feet above the sea, 25 miles south-east of Comayagua. T. is the largest and finest city in the state. In the vicinity are gold, silver, and copper mines; and in the north-west of the dep. of which T. is the capital, is the mountain of Agalteca, a vast mass of pure magnetic ore. Pop. 12,000.

TELLICHE'RRY, a seaport town and military station of British India, in the district of Malabar, 90 miles south-west of Seringapatam. The site of the town is very beautiful, and the neighbouring country highly productive, the low lands producing two, and in some cases three, crops of rice in the year. The cocoa-nut tree also grows in great abundance, and is put to many uses by the inhabitants. On account of its salubrity, T. has been called the Montpellier of India. There is a natural

breakwater abreast of the fort, formed by a reef of rocks running parallel to the shore, having a depth within suitable for ships of 500 or 600 tons. Pop. about 20,000.

TEPIC, a town of Mexico, in the state of Jalisco, on a height 400 miles north-west of the city of Mexico. T. is the residence, during the rainy season, of most of the wealthy inhabitants of the port of San Blas, about 25 miles distant. Pop. (1861) 10,000.

THEODORE, king of Abyssinia, otherwise described as Negus, Emperor or King of Kings of Ethiopia, a prince whose extraordinary career has excited much interest since war was declared against him by the English government. At the time when the article ABYSSINIA appeared in this work, the subject was not of much importance to English readers, and a few additional remarks are therefore necessary to explain the leading events in the life of Theodore. Abyssinia forms, it will be recollected, a table-land, which, although lying within the tropics, has, owing to its great elevation, a cool and equable climate. Its inhabitants, who have a Caucasian or European physiognomy, profess Christianity, acknowledge a bishop or abuna selected and consecrated by the Coptic patriarch of Alexandria, make use of a system of law based on the code of Justinian, and have otherwise preserved some share of the civilisation of ancient Rome. The Abyssinian Empire was at the height of its power in the 6th c., when it extended to the shores of the Red Sea, and even included a part of Southern Arabia. The Mohammedan conquests drove back the frontier to the limits of the table-land; and since the 7th c., the inhabitants have been engaged in a ceaseless warfare with negro tribes, and with the great Mohammedan powers. They have been surrounded on all sides by hostile races. The tradition of the great power of the Negus lingered in Europe throughout the middle ages; and although separated from the West, the Abyssinians continued to consider themselves one of the Christian and civilised communities. In the 15th c., when on the point of yielding to the invaders, they appealed to the Portuguese for assistance, and it was granted, on condition that they should abandon the rites of the Coptic Church, and yield unqualified submission to the pope. The promise was given, and the invaders were driven back. The royal family received the Roman Catholic priests, and professed the tenets of the Latin Church. They could not, however, induce the native clergy and the people to follow them; and their adoption of a foreign creed was the first step to the weakening of the royal power, which had been absolute for ages, and which rested on a firm basis of tradition and custom, particularly strong among a people in the stage of progress attained by the Abyssinians. The royal family still represented are of great antiquity, and are devoutly believed by their subjects to have sprung from Menelek, a son of Solomon and the queen of Sheba. The Abyssinian Church certainly dates from the 4th c., when the first bishop, or abuna, settled at Axum. The abuna is appointed and consecrated by the Coptic patriarch of Alexandria, whose supremacy he recognises. The dissensions introduced by Catholicism in the 16th c. were followed by invasions of the Gallas on the south, and the Turks on the north. The bitterness of the struggle with the latter has been increased by the large contribution exacted by the Egyptian government on the consecration of an abuna, and represented to be a tribute or acknowledgment of suzerainty. A frantic jealousy of the Turks among all ranks of Abyssinians is now one of the most prominent facts

in Abyssinian politics. The decay of the royal power in the 16th c. led to a phenomenon frequently repeated both in India and Europe. Just as the Merovingian kings of France became mere titular monarchs, the emperors of Ethiopia became 'puppet kings.' They were chosen from the royal stock by the great feudatories, but retained the mere insignia of royalty. When the great chiefs could not agree in the selection of a monarch, any one who found himself strong enough would march upon the capital, and place upon the throne one of the royal stock, and in his name retain supreme power, under the name of Ras (head or chief), until in turn unseated by a rival adopting the same course. In this way, there have been as many as twelve puppet emperors at one time, representing the same number of rival chiefs. The country has in consequence been kept in a perpetual state of revolution. From its great natural features, it must, however, be always divided into three leading parts: (1) Tigré, forming the northern promontory of the table-land, where the Geez, a Semitic dialect, is spoken, and through which passes the chief route to the Red Sea; (2) Amhara, the middle province, where the language is the non-Semitic Amharic, and in which is Gondar, the capital and seat of supreme power; and (3) Shoa, a southern prolongation of the table-land, where the language is also Amharic, but which is isolated from the rest of the country by intruding tribes of Gallas, an alien race. Among the minor provinces, the chief are Lasta and Waag, Semen, Godjam, and Kuara. In the last century, Gooska, a Galla adventurer, entered Amhara, the central province, and securing possession of the puppet emperor, assumed the title of Ras, and fixed his family in power at Debra Tabor. He was succeeded by his son, and his grandson, Ras Ali, who, within the last quarter of a century, confirmed the power of his family by successful military enterprises against the frontier tribes and the great chiefs, and by the marriage of his mother, Waizero Menin, a beautiful and clever woman, to Johannes, the nominal emperor. Such was the success of Ras Ali, that his supremacy was acknowledged by all the great chiefs except Dejaz Berro of Godjam, and that anarchy seemed about to cease for a time in Abyssinia. It was then for the first time that relations were opened between the central province and England. So early as 1810, while Great Britain was engaged in her struggle with Napoleon, Mr Salt was sent as her envoy to Abyssinia; but he went no further than Tigré, the Ras of which was treated as an independent sovereign. When the power of the French was destroyed in the eastern seas by the capture of the Mauritius, and the destruction of the French settlements in Madagascar, the English government ceased to take any interest in Abyssinia, and Mr Salt was recalled. One member of the English mission, however, a Mr Pearce, remained behind, and acquired the confidence of Dejaz Sabagadis, who, in 1816, on the death of Walda Selassié, acquired the government of Tigré. The favour manifested by the prince last named to Englishmen induced the Church Missionary Society to establish a mission within his territories, with which was connected Dr Gobat, since Anglican Bishop of Jerusalem. Tigré was conquered, however, by Dejaz Oubié of Semen; and the missionaries, who remained faithful to the family of the displaced chiefs, were compelled to leave the country. An opening was thus made for the Roman Catholics. They seized the opportunity, and under Padre de' Jacobis, a very able Neapolitan, established themselves in Tigré, and succeeded in making a strong impression on the population, among whom their leader became known as the

Abuna Yacob, and was invested with some share of the veneration bestowed on the native abuna. In consequence of the large sum exacted by the Egyptian government on the consecration of an abuna, the office had remained vacant for many years. To secure the influence of the native church, however, Dejaz Oubié sent a mission to Egypt to obtain the appointment of a new abuna, and the Padre de' Jacobis accompanied it, to secure, if possible, the selection of a priest favourable to Rome. He was, however, thwarted by the Coptic patriarch, who appointed Abba Salama, a young man, partly educated in the English Church Mission at Cairo, and who was afterwards to be mixed up with the fortunes of King Theodore. Shoa had also been brought into contact with Europe by a Protestant mission in 1838. Two years afterwards, the same country was visited by Major Harris; but owing to deplorable jealousy, no permanent result followed. The first direct intercourse with Amhara, the central province, was brought about by Mr John Bell, an officer of the Indian navy, who had married an Abyssinian, the daughter of a chief, and settled in the country. He had taken service in the army, in which he commanded the matchlockmen, and he had become the most trusted friend and adviser of Ras Ali. He liked the country, and thought it could be opened to English commerce and colonisation with incalculable advantage to both countries. In 1842, he was visited by Mr Walter Plowden, a Calcutta merchant, on his way to Europe from India, to whom he communicated his schemes, and imparted his own enthusiasm. The two Englishmen became bosom friends, and remained together five years in Abyssinia. In 1847, Mr Plowden proceeded to England to lay his views before the English government. He was less successful than he expected; but he convinced Lord Palmerston that under Ras Ali a central and permanent government had been established in Abyssinia, and that it was desirable to open commercial relations with the country. He was appointed consul, but unfortunately his headquarters were fixed at Massowah, a seaport within the Egyptian frontier, a choice which at once excited the suspicion, and wounded the vanity of the Abyssinians. On the 2d of November 1849, a treaty was entered into between Ras Ali and Mr Plowden, and there seemed every prospect of a close connection being established with this country, when all that had been done was rendered useless by the rise of T., and the entire destruction of the power of Ras Ali.

In the early part of the century, Kuara, a district of Amhara, south-west of Lake Tzana, was ruled by Dejaz Comfu. The brother of this frontier chief died young, leaving a widow in great poverty, and a son born in 1820, named Kassai, afterwards Theodore. She was compelled to seek refuge with her boy in Gondar. There she lived in great obscurity, earning her bread by selling *kosso*, a specific against tapeworm. What her rank was, is doubtful; and it is not known how far her son was justified in claiming for her descent from the family of the titular kings. Kassai was admitted to a monastery, where he spent many years; but his asylum was afterwards attacked by an insurgent chief, and he escaped with difficulty to Kuara. He joined the army of his uncle, then fighting the Turks; and he distinguished himself so much by courage, intelligence, activity, and tact, that he obtained a wonderful influence over his fellow-soldiers. Dejaz Comfu died suddenly, and his three sons quarrelled. To settle their dispute, Birru Goshu, chief of Godjam, was called in. He entered Kuara, and conquered the best part of it. Kassai, however, resisted him,

and at the head of a numerous band of soldiers took refuge among the mountains. He was there attacked by Waizero Menin, the mother of Ras Ali, who, as we have seen, had married the titular emperor, Johannes, and who at that time ruled Dembea, the district near Gondar, the capital. Kassai encountered her troops, defeated them several times, and recovered possession of Kuara. Ras Ali thought it prudent to come to terms, recognised him as governor of Kuara, and gave him his daughter in marriage. This alliance did not, however, reconcile Kassai and Waizero Menin. They again quarrelled, and again Kassai was victorious. He captured Waizero Menin, and compelled his father-in-law to acknowledge him as Ras of Kuara and Dembea. Ras Ali had, however, become alarmed at the power of Kassai, and determined to crush him. As representing the Ras, Birru Goshu attacked him with a powerful army, and compelled him again to seek refuge in the mountains of Kuara. In the following year, Kassai entered the field against Birru Goshu, conquered him, and slew him with his own hand. He then marched against Ras Ali, and drove him to Debra Tabor, the old stronghold of his family. There he maintained for a time a determined resistance, but he was compelled at last to yield, and he then sought refuge in the country of the Gallas, where he died. Kassai then attacked the Dejaz of Godjam, son of the chief he had killed, and defeated him. The whole of Amhara thus fell into his possession. Having secured the person of the titular emperor, he called upon Dejaz Ombié of Tigré and Semen to pay tribute to him. This demand was refused with insult. Such, however, was the power of this chief, that Kassai dreaded to attack him. The rivals met in February 1854, and to avert bloodshed, agreed to allow the magnates of the empire to decide which had the best right to the throne. The abuna was more under the control of Ombié than Kassai, and the latter felt that the weight of the church would be against him. Padre de' Jacobis, as already mentioned, had acquired considerable influence in Tigré. T. made advances to him, and offered that, if he, as head of the Latin Church, would support his cause, and crown him king, he would compel the people to adopt the Romiah rite. Dr Beke asserts that the Padre de' Jacobis accepted the offer. Kassai marched against Ombié, and in February 1855, a battle was fought at Debireakié, in which the latter was captured, as well as the Abuna Salama. Kassai, unscrupulously disregarding his promise to the Roman Catholic prelate, now made advances to the Abuna Abba Salama, and obtained his consent to acknowledge his descent from Solomon and the queen of Sheba, and to crown him emperor. The conditions exacted were, that Kassai should support the Coptic Church, and banish the Roman Catholics. A few days after the battle, Kassai was accordingly crowned by the abuna as Theodore of Abyssinia. It was not without reason that this name was chosen. According to an old tradition, a King Theodore was to reign in Abyssinia, conquer the kingdom of Solomon, and restore the ancient glory of Ethiopia. Kassai believed, or affected to believe, himself the man thus announced. He proclaimed himself a descendant of Solomon, but it does not appear that he ventured to ignore the titular king; on the contrary, since his coronation, he is represented as standing in the presence of the latter, naked to the waist, as is the custom of an Abyssinian servant in presence of his master. On the annexation of Tigré, T. resolved to attack Shoa, the third great province of the old empire. He invaded the country of the Wollo Gallas, defeated them, and reached Ankobar, the

southern capital. The people were frightened by the sudden death of the king, and submitted without a struggle. T. now resolved to extend his conquests to the Red Sea, and enter on a crusade against the Turks for the recovery of the sea-board. He had treated up till this time the conquered provinces with great leniency, generally leaving one of the ruling family in power, and to Mr Bell and Mr Plowden he extended the same protection they had from Ras Ali. He heartily adopted many of their schemes, and was anxious to open up intercourse with England. It was difficult, however, to negotiate with him. He believed himself to possess the same claim to respect as a European monarch, and was kept in perpetual torture by imaginary slights, and more especially by the respect shewn to the Turks, whom he regards as barbarians. His vanity and touchiness were aggravated by reverses. The conquest of Shoa had not long been completed, when the Dejaz of Godjam and the prince of Tigré rebelled, the latter being supported by the French. At the time when the Roman Catholic missionaries were banished by T., Dr Krapf and the Rev. Martin Flad entered Central Abyssinia to found a Protestant mission under the auspices of Bishop Gobat of Jerusalem. They proposed to introduce handicraftsmen, not priests, who were to follow their usual avocations, and, in addition, merely to read the Scriptures, and distribute copies in the native languages. The scheme met with T.'s approval. In April 1856, the first member of the mission arrived, and others followed. Encouraged by their success, the Rev. H. A. Stern afterwards went to Abyssinia as agent of the Society for Promoting Christianity among the native Jews or Falashas, and obtained the consent of the king and abuna to found another mission. He went back to Europe, but returned early in 1863, accompanied by Mr and Mrs Rosenthal. A third, known as the Scotch mission, was founded, and all were well received. The first quarrels of T. were with the diplomatists. He was indignant at the proposal made by the English Foreign Office to exercise jurisdiction over criminals in Abyssinia, without granting him reciprocal rights. In November 1855, he was still further irritated by our refusal to receive any embassy from him without an assurance that he was to renounce all idea of reconquering from Egypt the Abyssinian territory of which it had taken possession. At this period, our government are accused of having systematically ignored complaints against the Turks. They certainly, without justification, expressed great dissatisfaction with the failure of Mr Plowden to realise the advantages of intercourse with Abyssinia, although he, in a series of admirable papers, unfortunately not published at the time, proved that it had arisen from causes he could not have anticipated. Personally, Mr Plowden remained on the best terms with T., and if he had lived, all might have gone well. The consul, however, exposed himself to great risks. He was returning to Massowah from Gondar, when he and a company of fellow-travellers were attacked by Garod, a rebel chief. He was wounded, and died of the injury he received. The king and Mr Bell marched against Garod, and killed him. Garod's brother then killed Bell, and a horrible slaughter of the insurgents ensued. After the death of Mr Plowden, Captain C. D. Cameron was appointed consul. T. was not consulted, and the new consul was coldly received in October 1862. The Egyptians were at the time advancing within the northern frontier of Tigré, and Abyssinian Christians had been subjected to indignities at Jerusalem. T. resolved to appeal to the English and French governments, and wrote letters claiming their protection. That to the Queen

was forwarded to Aden, but unfortunately did not reach London until February 1863, when it was thrust into a pigeon-hole, and ignored or forgotten. In the meanwhile, Consul Cameron was directed to visit Sennaar, on the frontier of Egypt and Abyssinia, to judge of its fitness to become a cotton-producing country. The object of this journey was not explained to T., and he naturally believed it to be a visit by a spy to his enemies the Turks. His suspicions were not allayed when the consul, on his return to Gondar, could produce no answer to the letter. He had received a dispatch, but it simply ordered him to go back to Massowah, and not to interfere with Abyssinian politics. 'So your queen,' said T., 'can give you orders to return to Massowah, but she cannot send a civil answer to my letter to her. You shall not leave till that answer comes;' and the consul was detained on parole at Gondar. In reply to the French letter, M. Lejean was sent to Abyssinia. A written answer to T. was read, in which, as if it had been intended to irritate him, something was said of the protection accorded by the Emperor of the French to all Roman Catholics in the East. This aggravated the offence already committed by the French—that of aiding the prince of Tigré. The letter was torn and trampled upon, and M. Lejean, imprisoned for a few days, was ordered off to Massowah. T. declared he would no longer be 'humbugged by missionaries and consuls like a rajah of Hindustan,' and the European residents all felt that a crisis had come. In October 1863, Consul Cameron sent letters to Massowah. His messengers were stopped, deprived of their dispatches, and beaten. On the same day, Mr Stern, who happened to pay a visit of ceremony to the emperor, inadvertently gave him offence; and he and his two servants were ordered to be beaten. The servants died the same night. Mr Stern himself was so seriously hurt that his life was despaired of. His papers were then examined, and found to contain remarks derogatory to the emperor. He and Mr Rosenthal were arrested, and on the 20th of November, they were publicly tried with all the formalities of Abyssinian law—on a charge of having committed the *crimen læsæ majestatis*. Mr Stern was accused of having circulated the report in Europe of T. being the son of a beggar-woman who sold kosso, and of his not being the descendant of Solomon and the queen of Sheba; while Mr Rosenthal was accused of having said that the country would fare better under the Turks than Theodore. The prisoners were condemned to death, but the sentence was not carried out. Two days after the trial, dispatches arrived for Captain Cameron, but there was no reply to T.'s letter. Under these circumstances, the consul was injudicious enough to apply for permission to leave. He was arrested and thrown into the prison at Gondar with the missionaries, where they remained till the following summer, when they were removed to Magdala. The English government did not seem to interest themselves about the consul; but the case of the missionaries was warmly taken up by Lord Shaftesbury and the religious public. A letter of Captain Cameron's was published, in which he said: 'No release until an answer is sent to the letter to the Queen.' The subject was brought before parliament, and the government were compelled to search for this document. It was found in the pigeon-hole where it had been put, endorsed by Lord John Russell. It had been written in 1862; it was answered in June 1864. The reply was intrusted to Mr Hormuzd Rassam, a native of Mosul, who had been employed in diplomatic service at Aden. The choice of this envoy was most unfortunate—

he being, in the eyes of Theodore, a mere Turk, and therefore a spy and an enemy. He was not received till January 1866, and then a second error was committed. Mr Rassam accepted a large present from T., and did not, or was not enabled to repay it, as was expected, by a gift equal in value, although the necessity of doing so had been fully explained to the government. T. then sent the English envoy, who was treated as a mere beggar, to prison with the other captives. This was his first distinct breach of the law of nations. After this period, he conducted himself like a madman: he caused women and children to be tortured, dishonoured, and starved in an unheard-of manner. 'Out of 3,000,000 inhabitants,' says Dr Blanc in June 1867, 'he has destroyed more than a third by war, famine, and murder.' After some unsuccessful attempts to negotiate with T., through Mr Flad, in the early part of 1867, Lord Stanley, in April, ordered him within three months to deliver up the prisoners. He took no notice of the communication, and accordingly an expedition was fitted out at Bombay for the invasion of the table-land. The force consisted of upwards of 10,000 soldiers. Early in November the advanced brigade landed at Zulla, on the Red Sea. From this point, the expedition advanced successfully in spite of many difficulties, and, in the beginning of April 1868, came within sight of Magdala. On the 10th of April, near Magdala, T. gave battle to the British forces, and sustained a defeat so decided that he forthwith made submission to the extent of surrendering all the European captives in his power; and on the 13th, Magdala, into which he had retired, was stormed, and with little difficulty was taken possession of by our forces. Neither in the battle nor the assault was there any loss of life on the British side, only a few being wounded; the Abyssinians sustained a loss of 600 killed and 1500 wounded, the most notable among the former being T. himself, who was found dead, shot in the head.—See *The British Captives in Abyssinia*, and other works, by C. T. Beke, Ph.D.; the government blue-books; an article in No. 65 of the *Westminster Review*, New Series; the works of Harris, Rudolph, Lejean, and Dufton.

THERMO-DYNAMICS, or the **DYNAMICAL THEORY OF HEAT**, though literally merely the science of the relations of Heat and Work, is now very generally employed to denote the whole science of **ENERGY**. See **FORCE**. We propose in this place to give a general sketch of this grand modern generalisation, supplementary to what will be found in the article just referred to; but, for the sake of continuity, we must repeat a little of what was there given, though in a somewhat different form.

Energy is strictly defined as the power of doing Work (q. v.), and is of one or other of two kinds—*Potential* or *Kinetic*. A raised weight, a wound-up spring, gunpowder, and the food of animals, are instances of stores of potential energy. A missile in motion, wind, heat, and electric currents are instances of kinetic energy. Sound, Light, and other forms of Wave-motion (see **WAVE**), are all instances of mixed potential and kinetic energy.

The modern theory of Energy contemplates its

CONSERVATION,
TRANSFORMATION, and
DISSIPATION.

The **CONSERVATION OF ENERGY** is the statement of the experimental fact, that Energy is, like Matter (q. v.), indestructible and uncreatable by any process at the command of man.

The **TRANSFORMATION OF ENERGY** is the statement of the experimental fact, that any one form of energy may in general be transformed wholly or

partially into any other form. This used to be known as the CORRELATION OF FORCES. But it is subject to the condition derived from the first fact, that the portion transformed retains its amount unchanged. It is also subject to the law of DISSIPATION, or Degradation, which is a statement of the experimental fact, that Energy generally tends at every transformation to at least a partial transformation into heat; and that, once in that form, it tends to a state of uniform distribution, in which no further transformation is possible.

The original energy of the universe, therefore, though still of the same amount as at creation, being in a state of ceaseless transformation, has been in great part frittered down into heat, and will at length take wholly that final form.

The history of the grand discoveries which are briefly summarised in these few lines, has been much discussed of late—especially in the *Philosophical Magazine*—and is now pretty clearly ascertained.

Newton took the first great step. In a Scholium to his Third Law of Motion (q. v.), he lays down in a few clear words the Conservation of Energy as the embodiment of the experimental results known in his day with reference to forces and visible motions. Part of this statement of Newton's was afterwards reinvented under the name of Conservation of Vis-viva; but all that Newton really wanted to enable him to complete the Conservation of Energy was an experimental knowledge of the nature of Heat, Electricity, &c. That heat is motion of some kind, not matter, and that the laws of its communication are the same as those of the communication of visible motion, was experimentally proved at the very end of last century by Davy. Rumford had almost completed a proof a year or two before; but he had also made a very fair attempt to determine the 'Mechanical Equivalent' of heat—i. e., the quantity of heat which is equivalent to a given amount of mechanical work. That there is such an equivalent is at once evident by looking at Davy's discovery in the light of Newton's Scholium already referred to. But though the Dynamical Theory of Heat was thus really founded in 1799, it was not generally received. The first to recall attention to it was Séguin, nephew of the celebrated Montgolfier (from whom he states that he derived his views), who, in 1839, distinctly enunciated the equivalence of heat and mechanical work, and sought to prove by experiment that heat disappears, or is put out of existence, in the production of work from a steam-engine.

In 1842, Mayer published a short note, in which he enunciated the Conservation of Energy as a metaphysical deduction from the maxim, *Causa æquat effectum*. He made no experiments to prove this general statement, but he made a calculation of the mechanical equivalent of heat from the specific heats of air—assuming that when heat is produced by compression, its amount is the equivalent of the work spent in compressing. His result was erroneous, because his data were imperfect. But it appears that his assumption, quite unwarranted as it was, is really very nearly true for air.

In 1843, Colding, led also by some metaphysical speculations, propounded the doctrine, but endeavoured to base it upon actual experiments.

Finally, Joule (q. v.), also in 1843, published an experimental determination of the mechanical equivalent of heat (770 foot pounds as the work required to heat a pound of water one degree F.), which is within half per cent. of the most trustworthy results since obtained. Joule had been, since 1840 at least, making quantitative determinations of equivalence between various forms of energy; and was led to propound the general law of Conservation of Energy

by the only legitimate process—viz., experiment, as contrasted with metaphysical assertions of what ought to be. The complete foundation of the science on a proper basis is thus due to him; though, as we have seen, portions of it were established thoroughly by Newton and by Davy.

Before we consider what are the principal features of the theory as now developed, it is necessary to refer to the admirable investigations of Fourier and Carnot, which, though in some respects defective, must be considered as real advances. Fourier's great work, *Théorie de la Chaleur*, is devoted to the laws of conduction and radiation, i. e., to the dissipation, of heat, and is one of the most remarkable mathematical works ever written. Carnot's work, *Sur la Puissance Motrice du Feu*, is the first in which any attempt is made to explain the production of work from heat. It is unfortunately marred by his assumption, that heat is a material substance, though it is only fair to say that he expresses grave doubts as to the truth of this hypothesis.

(We borrow our notice of Carnot from a paper by Sir W. Thomson (q. v.) in the *Transactions of the Royal Society of Edinburgh*, 1849.)

He begins his investigation by premising the following correct principle, sadly neglected by many subsequent writers: 'If a body, after having experienced a certain number of transformations, be brought identically to its primitive physical state as to density, temperature, and molecular constitution, it must contain the same quantity of heat as that which it initially possessed.' Hence he concludes, that when heat produces work, it is in consequence of its being *let down* from a hot body to a cold one, as from the boiler to the condenser of a steam-engine. His investigation, though based on an erroneous hypothesis, is extremely ingenious, and forms the foundation of the modern theory. We give a sketch of it, preparatory to our account of the present state of the theory, and for this purpose we choose a somewhat hypothetical case, as simpler than the most common practical one. This is the case of a piston working air-tight in a cylinder closed at the bottom.

Suppose we have two bodies, A and B, whose temperatures, S and T, are maintained uniform, A being the warmer body, and suppose we have a stand, C, which is a non-conductor of heat. Let the sides of the cylinder and the piston be also non-conductors, but let the bottom of the cylinder be a perfect conductor; and let the cylinder contain a little water, nearly touching the piston when pushed down. Set the cylinder on A; then the water will at once acquire the temperature S, and steam at the same temperature will be formed, so that a certain pressure must be exerted to prevent the piston from rising. Let us take this condition as our starting-point for the cycle of operations. 1. Allow the piston to rise gradually; work is done by the pressure of the steam, which goes on increasing in quantity as the piston rises, so as always to be at the same temperature and pressure. And *heat is abstracted from A*, namely, the latent heat of the steam formed during the operation. 2. Place the cylinder on C, and allow the steam to raise the piston further. More work is done, more steam is formed, but the temperature sinks on account of the latent heat required for the formation of the new steam. Allow this process to go on till the temperature falls to T, the temperature of the body B. 3. Now, place the cylinder on B; there is of course no transfer of heat; because two bodies are said to have the same temperature when, if they be put in contact, neither parts with heat to the other. But if we now press down the piston, we do work upon the contents of the cylinder, steam is liquefied, and

the latent heat developed is at once absorbed by B. Carry on this process till the amount of heat given to B is exactly equal to that taken from A in the first operation, and place the cylinder on the non-conductor C. The temperature of the contents is now T, and the amount of caloric in them is precisely the same as before the first operation. 4. Press down the piston further, till it occupies the same position as before the first operation; additional work is done on the contents of the cylinder, a further amount of steam is liquefied, and the temperature rises.

Moreover, it rises to S exactly, by the fundamental axiom, because the volume occupied by the water and steam is the same as before the first operation, and the quantity of caloric they contain is also the same—as much having been abstracted in the third operation as was communicated in the first—while in the second and fourth operations, the contents of the cylinder neither gain nor lose caloric, as they are surrounded by non-conductors.

Now, during the first two operations, work was done by the steam on the piston; during the last two, work was done against the steam; on the whole, the work done by the steam exceeds that done upon it, since evidently the temperature of the contents, for any position of the piston in its ascent, was greater than for the same position in the descent, except at the initial and final positions, where it is the same. Hence the pressure also was greater at each stage in the ascent than at the corresponding stage in the descent; from which the theorem is evident.

Hence, on the whole, a certain amount of work has been communicated by the motion of the piston to external bodies; and the contents of the cylinder having been exactly restored to their primitive condition, we are entitled to regard this work as due to the caloric employed in the process. This, we see, was taken from A, and wholly transferred to B. It thus appears that caloric does work by being let down from a higher to a lower temperature. And the reader may easily see that if we knew the laws which connect the pressure of saturated steam, and the amount of caloric it contains, with its volume and temperature, it would be possible to apply a rigorous calculation to the various processes of the cycle above explained, and to express by formulæ the amount of work gained on the whole in the series of operations, in terms of the temperatures (S and T) of the boiler and condenser of a steam-engine, and the whole amount of caloric which passes from one to the other.

Though the above process is exceedingly ingenious and important, it is to a considerable extent vitiated by the assumption of the materiality of heat which is made throughout. To shew this, it is only necessary to consider the second operation, where work is supposed to be done by the contents of the cylinder expanding without loss or gain of caloric, a supposition which our present knowledge of the nature of heat shews to be incorrect. But it is quite easy, as seems to have been first remarked by J. Thomson in 1849, to put Carnot's statement in a form which is rigorously correct, whatever be the nature of heat. J. Thomson says: "We should not say, in the third operation, "compress till the same amount of heat is given out as was taken in during the first." But we should say, "compress till we have let out so much heat that the further compression (during the fourth stage) to the original volume may give back the original temperature." It is but bare justice, however, to acknowledge that Carnot himself was by no means satisfied with the caloric hypothesis, and that he insinuates, as we have already seen, more than a mere suspicion of its correctness.

If we carefully examine the above cycle of operations, we easily see that they are reversible, i. e., that the transference of the given amount of caloric back again from B to A, by performing the same operations in the opposite order, requires that we expend on the piston, on the whole, as much work as was gained during the direct operations. This most important idea is due to Carnot, and from it he deduces his test of a perfect engine, or one which yields from the transference of a given quantity of caloric from one body to another (each being at a given temperature) the greatest possible amount of work. And the test is simply that the cycle of operations must be reversible.

To prove it, we need only consider that, if a heat-engine, M, could be made to give more work by transferring a given amount of caloric from A to B, than a reversible engine, N, does, we may set M and N to work in combination, M driven by the transfer of heat, and in turn driving N, which is employed to restore the heat to the source. The compound system would thus in each cycle produce an amount of work equal to the excess of that done by M over that expended on N, without on the whole any transference of heat; which is of course absurd.

The application of the true theory of heat to these propositions was made in 1849, 1850, and 1851 respectively, by Rankine, Clausius, and W. Thomson. Rankine employed a hypothesis as to the nature of the motion of which heat consists, from which he deduced a great many valuable results. Clausius supplied the defects of Carnot's beautiful reasoning; accommodating it to the dynamical theory by a very simple change, and evolving a great number of important consequences. But by far the simplest, though at the same time the most profound, writings on this subject, are those of W. Thomson, to be found in the *Transactions of the Royal Society of Edinburgh*; and these must be consulted by any reader who desires to have a clear statement and proof of thermo-dynamical laws, not complicated by unnecessary hypotheses or formulæ, and yet perfectly general in its application.

In its new form, thermo-dynamics is based on the two following laws:

Law I. (Davy and Joule.) *When equal quantities of mechanical effect are produced by any means whatever from purely thermal sources, or lost in purely thermal effects, equal quantities of heat are put out of existence, or are generated.*

Law II. (Carnot and Clausius.) *If an engine be such that, when it is worked backwards, the physical and mechanical agencies in every part of its motions are all reversed, it produces as much mechanical effect as can be produced by any thermo-dynamical engine, with the same temperatures of source and refrigerator, from a given quantity of heat.*

The proof of this second law differs from that of Carnot (already given as regards reversible engines) by being no longer based on the supposition of the materiality of heat, but on the following axiom, in some of its many possible forms—It is impossible, by means of inanimate material agency, to derive mechanical effect from any portion of matter by cooling it below the temperature of the coldest of the surrounding objects. It will be easily seen that the pair of engines (one reversible) before mentioned would, if worked in combination, form a perpetual motion; and, besides, would constantly transfer heat from a colder to a warmer body.

One of the immediate and most important deductions from these principles is—that only a fraction of the heat employed in any engine is converted into useful work (the remainder being irrecoverably

lost). This fraction was shewn by Thomson to be capable of expression as

$$\frac{S - T}{S};$$

where S and T are the temperatures of the source and condenser, *measured from the absolute zero of temperature*. See HEAT. Thus, an air-engine, in which a far greater range of temperature can be safely used than in a steam-engine, employs effectively a much larger portion of the heat supplied to it; and there is no doubt that air-engines would supersede steam-engines, if we could get a material capable of enduring the great heat required.

THERMO-ELECTRICITY AND THERMO-MAGNETISM. If the ends of an iron wire be attached by twisting or soldering to the extremities of the copper wire of a galvanometer, and one of these junctions be heated, the galvanometer indicates the passage of a current in the circuit in a direction from copper to iron through the heated junction. The first application of the theory of energy to this phenomenon is of course as follows: Since heating the junction produces the energy of the current, part of the heat must be expended in this process; though it is of course entirely recovered as heat in the circuit, if the current be not employed to do external work. The existence of the current from copper to iron is thus associated with the cooling of the junction; and it had been experimentally shewn by Peltier, that if an electric current be passed through a circuit of iron and copper, originally at the same temperature throughout, it produced cold when passing from copper to iron, and heat when passing from iron to copper. If the two junctions be maintained each at a constant temperature, a constant current passes from the warmer to the colder junction through the iron wire; and by the conservation of energy, the heat developed in the circuit (together with the equivalent of the external work done, if the current be employed to drive an electro-magnetic engine) is equal to the excess of the heat absorbed at the warmer junction over that given out at the colder, precisely as in the case of a heat-engine. So far the process presents no difficulties. But it was discovered by Cumming in 1823, that not only is the strength of the current *not* generally proportional to the difference of temperatures of the junctions, but that if the difference be sufficiently great, the current may, in many cases, pass in the opposite direction. Thus, in the copper-iron circuit, at the temperature 300° C. of the hot junction, the current passes through it from iron to copper. Thomson (Bakerian Lecture—*Phil. Trans.* 1855—'On the Electrodynamic Properties of Metals') applied the principle of energy to this case, and derived from it the conclusion, that one of three things must happen, the most unexpected of which was found by experiment to be the actual one—viz., the startling result, that *a current passing in an iron bar or wire from a hot to a cold part produces a cooling, but in copper a heating, effect.* This very remarkable discovery, which, taken in connection with that of Peltier, gives the key to the whole subject of thermo-electricity, has been recently made the subject of a valuable experimental investigation by Le Roux (*Annales de Chimie*, 1867).

The theory of such phenomena (and of others far more complex, involving, for instance, crystalline arrangement), in complete accordance with the conservation of energy, has been given by Thomson (*Trans. Royal Soc. Edin.* 1854); but it would be inconsistent with the character of this work to enter into any details on so abstruse a subject. A similar remark must be made regarding his application of

the principle to the subject of thermo-magnetism, or the relation of the magnetisability of various substances to their temperature; one or two of his results may, however, be mentioned. Thus, iron at a moderate or low red-heat experiences a heating effect when allowed to approach a magnet, and a cooling effect when slowly drawn away from it; while in cobalt, at ordinary temperatures, exactly the opposite effects are produced. Similar effects are in general produced when a doubly-refracting crystal is turned in the neighbourhood of a magnet.

THOUROUT, a town of Belgium, in the province of West Flanders, 11 miles west-south-west of Bruges. There are manufactures of starch, mustard, hats, and wooden shoes. T. was a place of great commercial importance in the middle ages. Pop. (1863) 7941.

TILLICOULTRY, a manufacturing town of Scotland, beautifully situated in the county of Clackmannan, on the Devon, nine miles east-north-east of Stirling, with which it is connected by railway. There are large manufactures of shawls and plaidings. Pop. (1861) 3684.

TINNEVELLY (*Tiru-nel-véli*), chief town of the British district of the same name, is situated near the left bank of the river Chindinthoora, 350 miles south-west of Madras. The town of T. is connected with the town and military station of Pallamcottah, on the opposite bank of the river. Pop. about 20,000.

TOBACCO-PIPE FISH (*Fistularia tabaccaria*), a fish of the family *Fistulariæ* (q. v.), found in the tropical parts of the Atlantic Ocean, and remarkable for its form, which is very elongated; the head also is prolonged into a very long snout, and from between the lobes of the short, widely-forked tail, proceeds a long whip-like ray. It is greenish olive, with blue stripes and spots.

TODMOR'DEN, a market-town of England, in the county of Lancaster, on the border of Yorkshire, 8 miles north-north-east from Rochdale, on the Manchester Railway. The town is well built, has several churches and schools, and manufactures of cotton. Coal abounds in the vicinity. The town proper of T. is composed of houses belonging to three townships, the pop. (1861) being 6458.

TORTOISE BEETLE, a genus of coleopterous insects of the section *Tetramera*, family *Cyclicæ*, and tribe *Cassidariæ*. The popular name is derived from the resemblance of general form to that of the tortoise. There is also often a considerable similarity in colouring. The body is generally somewhat oval or circular, sometimes nearly square. *Cassida viridis*, an insect about a quarter of an inch in length, is not uncommon in Britain. It lives on thistles.

TOTEM. The ruder races of men are found divided into tribes, each of which is usually named after some animal, vegetable, or thing which is an object of veneration or worship to the tribe. This animal, vegetable, or thing is the *totem* or *god* of the tribe. From the tribe being commonly named after its totem, the word is also frequently employed to signify merely the tribal name. Numerous tribes with totems exist in America, in Australia, the South Pacific Islands, and in Central Asia; and there are some reasons for thinking that such tribes were once numerous even in Europe among races belonging to what is called the Indo-European division of the human family.

Among the Red Indians of America, the following are totems of tribes existing or known to have existed: the Wolf, Bear, Beaver, Turtle, Deer, Snipe, Heron, Hawk, Crane, Duck, Loon, Turkey, Musk-rat, Sable, Pike, Cat-fish, Sturgeon, Carp,

Buffalo, Elk, Reindeer, Eagle, Hare, Rabbit, and Snake; the Reed-grass, Sand, Water, Rock, and Tobacco-plant. Among the tribes of native Australians, the totems are similarly, for the most part, selected from the fauna of the country. The totems of the Kirghiz tribes of Central Asia are all of them animals to which (in explanation of their reverence for them) the tribes trace back their descent.

It has been suggested that the explanation of the crests and emblems of the now disrupted tribes and clans of our own country, and of Europe generally, is to be found in the supposition, that the creature or thing on the crest was originally the totem of the clan or tribe. On this supposition, the widespread clan Chattan or Cattan, for instance, which is represented in the Scotch Highlands, and can be traced in France, Germany, and Egypt, would fall to be recognised as the *Cat* tribe, the cat having once been its totem, as it is still its crest or emblem. It has also been thrown out, that many of the mythical traditions of ancient Greece admit of a reasonable meaning, if we suppose that there were anciently in Greece tribes with totems—bull, boar, and lion tribes; snake, ant, and dragon tribes. These suggestions have not yet been put to the test of a thorough investigation; but so far as inquiry has gone, the results are in favour of the conclusions to which they point as to the early condition of human tribes all over the world. A single instance may be given of success in tracing back a totem to old times and in widely separated countries. There are numerous existing Snake tribes both in America and the South Sea Islands, and there is something like *proof* that the snake was the totem of very many and powerful ancient races. Its worship can be traced among Semitic races; there are traces of it in the traditions of the Pelasgi; there are proofs of it among the Celts; and the most magnificent ecclesiastical architecture in the world is that of the Nagas—the serpent-worshippers of Cambodia—still existing, and only recently brought to light. We may believe that, in the period of primitive animal-worship, when the serpent was a creature of so much importance, other animals also had their worshippers, and that snake-tribes were not the only tribes with animal totems in those times, any more than they are among existing primitive peoples.—See *Cambrian Journal*, vol. iii., 2d series, p. 149; *Grey's Journals*, vol. ii. chap. xi.; Mitchell's *Russians in Central Asia*; Latham's *Descriptive Ethnology*; Sydenham's *Baal Duretrigensis*; and foot-note to *Kinship in Ancient Greece*, by J. F. M'Lennan; *Fortnightly Review*, 15th April and 1st May 1866.

TRADES' UNIONS, in their character of benefit and sick societies, do not fall within the range of this article. We have principally to consider them as associations of workmen against employers, for the purpose of gaining, either in time or money, a larger share of the profits of their trade. A brief historical sketch of the growth of the principle of combination may fitly introduce the subject.

In one form or other, combination has always existed, ever since the employed and employing classes became distinguishable from each other. For a long time after the Conquest, the inhabitants of England were of two classes, freemen and slaves. These relations not permitting work for wages, there could be then no combination in the modern sense. About the middle of the 13th c., we find that wages had begun to be paid, so that for 600 years there have been labourers receiving a money price for their services, competing for employment, and arranging terms with employers. The power of legislation was, however, with men who believed

their interests antagonistic to those of the workmen, and its complexion was always favourable to masters. When, after the great pestilence of 1349, the reduced number of labourers demanded better pay, it was enacted that carters, ploughmen, and agricultural servants generally should be content with their previous rate of liveries and wages; they were to continue to be paid in kind where payment in kind had been customary; they were forbidden to hire themselves for the day, but must take service for a year or other fixed period; a rate of wages was fixed for weeders, haymakers, mowers, and reapers; and their hiring for the future was to be in public. A little later, in 1363, the diet and clothing of artificers and servants were fixed by act of parliament, and clothiers were required to make, and tradesmen to sell, cloth of a regulated quality at a regulated price. The rate at which labour should be purchased was fixed after this fashion for almost two centuries, and the practice declined solely because of the impossibility of preserving it. But even within the last 150 years, a relic of the old superstition revived, so characteristic as to be worth notice. A tariff of wages, drawn up in 1725 by the Manchester justices, declares that any workman conspiring to obtain more than the rate thereby fixed, should for the third offence stand in the pillory, and lose an ear. Economical error, it will be seen, is by no means the monopoly of the poor.

One of the earliest forms assumed by combination is shewn by the statutes, passed about 1400 A.D., which excluded from city labour all who had been trained to the plough up to the age of 12 years. The evasion of these acts was the subject of bitter complaints from the city inhabitants, whose practical union against agriculturists was defeated by the sending of country children into towns as apprentices before they reached that age. For generations, this jealousy of corporation against corporation continued with more or less intensity. Manufactures were mainly in the hands of monopolists, and merchants were successful or not, according as they happened to be the fortunate possessors of privilege, or the victims of unjust restriction. Town manufacturers did all they could to prevent the growth in rural districts of industries similar to their own. Edward VI.'s parliament was induced to legislate against machinery, and to prescribe limits beyond which the woollen trade should not be carried on. Guilds and corporations multiplied all manner of vexatious and impolitic laws, devised for the maintenance of their own arts and trades, and they watched with the utmost jealousy the attempts of outsiders to gain admission. In some respects, this still remains true of the action of incorporated trades; but, with a few sad and shameful exceptions, the conduct of associations, whether of masters or workmen, has partaken in the general improvement of modern days.

In the more ancient forms of associated labour, such as guilds and chartered companies, combinations such as those which now prevail could not exist. There were no masters and workmen as separate and opposed classes. Producers were united as against the community, and they had no reason, so long as the guild was prosperous, for internal dissension. When, by the abuse of their power in prosperity, they incurred hostile legislation, they became disintegrated; workmen were employed who had never been apprentices; and ultimately the owners of capital and the owners of labour became distinct and often opposing camps. Instead of a guild or trade being any longer a compact monopolist body, acting for itself against the community, the tendency was thenceforward for combination of one section against the other.

Trades' unions, organised for purposes such as those which contemporary unions contend for, have existed for more than three centuries. So early as 1548, a statute of Edward VI. is directed, amongst other culprits, against certain 'artificers, handicraftsmen, and labourers,' who had 'sworn mutual oaths' to do only certain kinds of work, to regulate how much work should be done in a day, and what hours and times they should work. The usual penalties of fines, pillory, and loss of ears were to follow a breach of its enactments. Add the regulation of wages to the objects enumerated in this statute, and we have in effect the trades' unions of the present day. Many fruitless acts were afterwards passed to prevent combinations for raising wages. So long as a tacit bond existed, and unquestionably one did and does exist, amongst employers, reprisals on the part of workmen were certain, and the only question was, whether the right of combination should be recognised by the law, or whether the parties who had recourse to it should be driven into secrecy and illegality. But it was not till 1824 that the legislature had sufficient wisdom to repeal the numerous and vexatious acts of parliament by which it had been sought to prevent the union either of masters or workmen. By the celebrated act of that year, the combination of either workmen or capitalists was legalised, so long as the unions refrained from violent interference with persons who might refuse to join them. This act was supplemented by another, passed in 1825, which in effect declared legal all combinations to settle rates of wages or hours of work, and illegal all such as aimed at other methods of controlling employers in the use of capital, or in processes of manufacture.

A modern trades' union is a rather complex organisation. The best definition of them is perhaps the one given by the Social Science 'Committee on Trade Societies,' appointed at Bradford in 1859, and which published its Report in 1860. The committee included Mr Charles Buxton, Dr Farr, Professor Fawcett, Mr W. E. Forster, Mr J. M. Ludlow, Rev. F. D. Maurice, Mr Horace Mann, Mr Thomas Hughes, and many others almost equally well known, and its investigations were very searching and valuable. Indeed, its Report is by far the best repository of facts on the subject up to the present time. A trade society is therein defined as 'a combination of workmen to enable each to secure the conditions most favourable for labour.' The capitalist's accumulations afford him an advantage which the labourer, without association, does not possess. The funds of the union are intended to supply this deficiency. As accessories, the unions collect funds for other purposes, such as benefit societies, insurance of tools, libraries, and reading-rooms; but their trade objects are those with which we are especially concerned. The following means of assisting and defending the trades associated are enumerated by the committee as now in general use—1. Publishing periodically the state of the trade in different parts of the country; 2. Keeping registers of men unemployed and of masters wanting men; 3. Assisting men from town to town in search of employment, and occasionally to emigrate; 4. Regulating the number of apprentices in the trade; 5. Maintaining men in resistance to employers; 6. Regulating number of working-hours, and preparing trade-rules; 7. Organising strikes.

The advocates of the unions insist that they are the only means by which workmen can defend themselves against the aggression of employers. It is argued that the individual labourer has no chance of resisting the capitalist on equal terms; that starvation treads too closely on his heels to permit

his successfully opposing a reduction of his wages, however arbitrary or unjust. It is urged that associations of employers are practically universal, and that their object is mainly to secure for themselves the largest possible share of the profits which are the product of capital and labour united. It is further said, that in the event of any depression of trade, the masters invariably attempt to reduce wages; and that when trade improves, they defer as long as possible the restoration of the former rate. Thus, workmen are the first to feel commercial disaster, and the last to benefit by better times. Any attempt to remedy this state of things by individual action would, it is conceived, be abortive. The capitalist might easily do without the services of any single labourer, while to the latter the loss of employment might be ruin. Association on the part of the employed class becomes, therefore, a necessity, and their organisation puts them at once much more nearly on an equality with employers when negotiating either as to rates of wages or terms of labour. That in both these matters there is a constant gravitation against the workman seems to be admitted by most who have considered the subject, and there is difficulty in suggesting any effective resistance to the downward tendency, except that of combination. Unionists point to many regulations in the interests of workmen which combination has enabled them to introduce, and while they freely admit that in numerous instances the contest between labour and capital has resulted in the apparent defeat of the former, yet they assert that, in the long run, most of the points contended for have been gained. They maintain that, in very many trades, they have succeeded in preventing such abuses as overtime being developed into a system of extortion; of continuous fluctuation of wages, which they conceive to be in all ways disastrous and demoralising; of numberless other forms of oppression and injustice, which any one man would be powerless to resist; and that, in short, the unions have contributed, more than any other agency, to make 'the workman's life regular, even, and safe.' Further, it is contended that the necessity for strikes will become continually less as organisation becomes more perfect and uniform; the just limits of their action will be more fully comprehended; the sufferings and losses of past strikes will act as a warning against too precipitate action in the future, either on the part of masters or men; and that, in the end, the main results of combination will be secured, without the necessity of having recourse to the arbitrament of force, either in the shape of strikes or lock-outs—the latter of which, indeed, is only a strike of the employers against the employed.

Yet it cannot be concealed that against this catalogue of uses may be set many and serious evils. Some unions dialike the exertion of special or superior ability by any of their members, deeming it an injustice to the rest that one should gain higher pay or win a loftier position. In many cases, as a matter of deliberate policy, they set themselves against and discountenance any elevation of the standard of labour, and so act as an effectual bar to the industrial progress of their class. In other instances, strikes are determined upon by unions at times when the position of the market renders success impossible, resulting in severe and prolonged suffering; while in some 'highly skilled and limited trades,' a far higher rate of wages has been enforced for a time than the value of the labour performed would justify, in the end materially checking production, or transferring the industry itself to other countries. The same effect has been produced by the arbitrary enforcement, in some branches of

manufacture, of obnoxious restrictions upon the hours and mode of working. Thus, Birmingham lost much of that portion of its hardware manufacture which is now carried on by machinery, in consequence of the resistance offered by the Birmingham artisans to the introduction of machine-labour; and the steel manufacture has begun to migrate from Sheffield, on account, it is asserted, of trades' union dictation. It is of course obvious that some branches of labour, if interference were pushed too far, might in this way be transferred, not to other towns only, but to other countries. There is, moreover, another and serious class of objections. There can be no doubt that unions foster an unfortunate spirit of antagonism. Being constantly and consciously on the defensive, they come at last to suspect evil in every movement, and to put a sinister interpretation on every action of employers. The special interests of the trade affected are too often the only objects cared for; and narrow, selfish, and unjust regulations are enacted for its supposed benefit. One trade is isolated from another; one class of labourers fences itself off against incursions upon its peculiar territory, and tries, by the limitation of the number of apprentices, the enforcement of objectionable terms of service, and other coercive methods, to remain a close monopolist corporation. It is needless to point out how injuriously such a policy affects the working-classes generally, and what a complete subordination it implies of the general well-being to the desired prosperity of a small and selfish number. In some trades, the practice of coercion has grown into systematic terrorism and crime. The Sheffield grinders and the Lancashire brickmakers began with merely refusing to work with non-unionists; but their methods of procedure have ended in frequent brutal and murderous outrage. The revelations of the special commissions of 1867 are among the saddest contributions to English history.

One of these special commissions—that of Mr Overend and his colleagues at Sheffield—is of sufficient importance and interest to warrant rather special reference. Out of about sixty trades' unions in that town, thirteen are proved to have promoted or encouraged outrages of various degrees of criminality, from theft and intimidation up to personal violence and murder. The most ordinary method of coercion in use bears the name of 'rattening,' and it is employed to enforce payment of contributions to the unions, and to compel obedience to their rules. If any workman fall into arrear with his payments, or infringe the rules of the trade to which he belongs, his wheelbands, tools, or other materials of work are secretly removed, and held in pledge, until he submits to the requirements of the union. This is done most frequently under the direct orders of the union officers; but sometimes a private member 'rattens' another, who is known to be in some way at issue with his society, and takes the risk of his action being adopted by the remainder. In the majority of cases, on due submission and a moderate payment, the property rattened is restored to its owner. The practice is defended on the ground that it is the readiest and most effectual means of compelling the regular payment of contributions to the union funds, and of enforcing obedience to union orders. So thoroughly is it understood that rattening is the work of a trade society, that a man whose tools are taken never thinks of applying to the police for restitution; he communicates with the secretary of the union which governs his trade. In cases of contumacy on the part of a member, it is sometimes attempted to saddle his employer with the cost of the rattening, even when he is no party to the dispute, on the

ground, that he ought to compel his workmen to comply with the rules of the union. Rattening is generally successful in securing its ends; but if it fail, an anonymous letter is sent to the refractory person, threatening vengeance in the event of further resistance; and in only too many instances, the threats have been carried out to the last extremity. Thus, in 1854, a man named Elisha Parker had his house blown up by gunpowder, his horse was hamstrung, and he himself disabled by a pistol-shot, because he worked with non-union men, after being warned to leave his employment. In 1857, James Linley was shot at and wounded for changing his business of grinding scissors for that of grinding saws, and keeping a greater number of apprentices than the rules of the trade prescribed. As he still persisted, he was shot to death with an air-gun in 1859. At other times, powder has been mixed with the filings or other materials near the working apparatus of obnoxious persons, who have often suffered serious injuries from its explosion. The list of outrages, fatal and other, might be largely extended; but those we have given are not unfair representatives of the whole.

The bellows-cutting by the chainmakers of the midland districts, during their strike of 1859, are somewhat analogous to the rattening at Sheffield; and disclosures of similar practices were made at the inquiry before Mr Pickering and others in Manchester, also in 1867. We have not space to go into detail; but the examples of Sheffield, Dudley, and Wolverhampton were faithfully repeated. Powder explosions, personal injuries, the wholesale destruction of bricks by trampling upon them while soft, a shed destroyed by naphtha, the insertion of needles into the clay, so as to disable the workmen: such were among the characteristic confessions made by the witnesses. Among other reasons given for a strike was one that an employer had himself 'set a brick,' a task expressly reserved for brick-setters; and among the restrictions on trade was one forbidding the use in Manchester of bricks not made within the Manchester district, a circle about eight miles across.

Although in very many instances strikes have been begun and concluded without the intervention of trades' unions, yet, as a matter of fact, all the more notable strikes have either been organised by them, or had their direct support; and of late, the tendency has been to associate the unions of different trades into one body, so far as this particular policy is concerned. This article would therefore be incomplete without a brief reference to some of the more remarkable contests between masters and workmen.

Among the leading strikes, few, if any, have occupied the attention of the public more than the struggle between the Amalgamated Society of Engineers and their employers, which took place in 1851-1852. It originated in the determination of the workmen to abolish piecework and overtime. The dispute was further complicated through a demand made by the mechanics at Messrs Hibbert & Platt's works, in Oldham, insisting that certain self-acting machines in use there should be attended to by skilled labourers only. Thirty-four Lancashire firms entered into a written agreement to meet any action on the part of the men by the immediate closing of their establishments, which furnished employment to 10,000 people. A similar resolution was adopted by the master engineers of the London district. The men left work on the 1st of January 1852, and the works were formally closed on the 10th. The strike virtually ended on the 30th March, when the men conceded the points in dispute, with the exception of an obnoxious

· TRING—TUBE-WELL.

declaration insisted upon by the masters, that none of the men employed should, for the future, either directly or indirectly support trades' unions. The cost of the strike is understood, besides the enormous loss of wages, to have exceeded £40,000, including moneys contributed to non-society men. Great numbers of the men emigrated, and fearful suffering was endured by thousands of families. It is right to state, that a careful consideration of all the facts of this strike leads to the conclusion, that although the men were in error at the beginning of the contest, they were more moderate and candid during its progress than the associated masters, and that a proposal on their part to refer the questions in dispute to arbitration was refused. The Amalgamated Society still exists and is prosperous. In 1860, its members exceeded 17,000.

The strike of 1853 in the cotton trade at Preston was also met by a lock-out. About 18,000 people were thrown out of work. The struggle lasted seven months, and during its progress, public feeling was keenly roused. The 10 per cent. advance in wages contended for was successfully resisted by the masters, the last chances of the workpeople being destroyed by the depression of trade consequent upon the outbreak of the Russian war. The cost of the strike to the workmen and their friends, in actual money paid, was £105,000.

In 1859, there occurred a strike and lock-out in the building trades of London. The object of the strike was to reduce the working day from ten to nine hours, the existing rate of wages being retained. It was met by the simultaneous closing of 225 building establishments, at which 24,000 men were employed. The contest lasted for nearly seven months, and ended in the surrender of the men, after an enormous loss in wages and trade funds. No less than £23,000 was contributed by other trade societies, in aid of the men concerned in this dispute.

It must not be considered, notwithstanding the examples given, that all strikes are unsuccessful, or that they are without effect, even when apparently crushed. There are many which succeed at the time, and many more soon afterwards. After the defeat just described, the carpenters of London, by a second strike, obtained, in 1865, an increase of 10 per cent. in wages, and the same rate is now being extended to the other branches of the building trade. In other instances, where visible results are not shewn, the lessons of preceding contests are not forgotten, but have a manifest influence on the conduct of both masters and men. They enforce discretion, and induce more moderate measures of procedure. Besides, it is observed that the rate of wages of those trades in which unions prevail is higher than in those not united; that, in the same trade, the wages of unionists are higher than those of non-unionists; and that a general rise of wages is rarely conceded without the intervention of societies. While the relations of employer and employed remain what they are, it is difficult to see how the latter can secure their fair share of the results of labour without having recourse to combination, and occasionally to the dangerous policy of a strike. But it is easy to push antagonism to excess on either side. Probably, the ultimate solution of the problem will be found in the associated action of capital and labour, on different principles from those at present common. Co-operation (q. v.), in some form, will, in all probability, be the friendly meeting-ground of the two now opposite forces. Its effects, we are inclined to believe, will be seen in the greater efficiency of labour, the development of a higher character both among workmen and employers, and the growth of a friendlier feeling

between classes now unfortunately too much estranged from each other.—Fawcett's *Manual of Political Economy*; Mill's *Political Economy*; Wade's *Middle and Working Classes*; Report of the *Social Science Committee on Trades' Societies*, 1860.

TRING, a town of Hertfordshire, England, 32 miles north-west from London, near the right bank of the Ouzel, a branch of the Ouse. It is a neatly built town; has manufactures of silk, canvas, and straw-plait, and is a station on the London and North-western Railway. The Grand Junction Canal passes not far from it. Pop. (1861) 3130.

TUBE-WELL is an American contrivance, introduced into England in 1867, having for its object the obtaining of a small supply of water in a very short space of time by the application of a limited amount of manual power.

The apparatus comprises three parts—a tube or well, a rammer or monkey, and a pump. Fig. 1 shows the several parts, and fig. 2 the state when driven into the ground. The tube, AA, consists of an iron pipe about 1½ inch diameter, made in pieces of convenient length, which can be screwed together end to end. The pipe terminates at the lower end with a solid tempered steel point, and is perforated for about 16 inches from the end with small lateral apertures. The pipe is driven a short way into the

Fig. 1.

Fig. 2.

ground, just sufficient to keep it upright without falling, and is temporarily kept in that position by hand. A strong iron clamp, DD, is fixed to the tube by clamping-screws at a short distance above the ground; and another clamp, BB, is similarly fixed higher up. Two pulleys are supported by the upper

clamp. The rammer or monkey, CC, consists of a 56-lb. iron weight, which slides up and down the tube, encircling it like a ring or belt. The rammer, being raised by two men, is allowed to fall with its full weight on the lower clamp; thus giving a series of blows which drive the tube into the ground. When the lower clamp becomes level with the surface of the ground, it is raised up the tube; as is likewise the other clamp, which supports the two pulleys. Successive lengths of tube and successive shiftings of the clamps afford the means of enabling the perforated end of the tube to reach soil whence water can be obtained. When the symptoms appear of water having been reached, at CC, a small suction-pump, shewn at the top of fig. 2, is applied, and the water pumped. It is only when water is expected to be reached at a moderate distance below the surface that this apparatus is available, as it is not powerful enough for great depths, nor is the bore of the tube sufficient for a large influx of water; but the required conditions being found to exist, the apparatus saves a large amount of ordinary boring. As the water is pumped up, the loose sand and gravel disappear from the point of the tube, allowing the formation of a small pool or well (BB, fig. 2); while small pebbles which collect around the perforations act as a sort of filter. The tube can be extracted from the ground by forcing the rammer upwards against the upper clamp.

During a trial of this apparatus in the cricket-ground at Old Trafford, Manchester, the tube was sunk to a depth of 10 feet in 22 minutes, and water had been reached in even less than that time. Such a form of well, it is considered, will be free from the liability of receiving dirty surface-water; and no accident is possible from foul air or from the falling in of the sides. A well 15 feet deep was sunk in one hour in the Botanical Gardens at Manchester, and excellent water reached. Another was sunk in the grounds of St Cloud in half an hour, and pumped up water at the rate of 20 litres (18 quarts) per minute. The inventor accompanied the American Federal army, and enabled the troops frequently to obtain water by the aid of these pumps. On one occasion, to try the capabilities of the tube, he sank one to a depth of 160 feet, at Ithaca, in New York state. Tube-wells have been sent out with the British military force to Abyssinia.

TUNKERS, a religious sect, occupying settlements in New England, New York, Pennsylvania, Ohio, Indiana, &c., and thus pretty widely scattered throughout the northern and middle parts of the United States. They are nowhere numerous, and are chiefly occupied in the cultivation of the soil. The name which they take for themselves is simply that of Brethren, and they profess that their association is founded on the principle of brotherly love. The name T. is of German origin, signifying Dippers, and is due to their dipping in baptism. It is very commonly, by corruption, pronounced and written *Dunkers*. In the vicinity of their settlements, they are generally known as the *Harmless People*. They derive their origin from a small village on the Eder in Germany, but have been an exclusively American sect since the beginning of last century, when they all emigrated to America. They had 52 communities or churches in 1859, and their number is estimated as about 8000. They reject infant baptism, and have no ministers specially devoted to the ministry as a profession. Every brother is allowed to stand up in the congregation and exhort; and when one is found particularly apt to teach, he is ordained by laying on of hands with fasting and prayer, and is expected to devote himself in some measure to the ministry, although without any stipend or pecuniary

reward, even if his own crops should suffer by his neglect of them. There are deaconesses as well as deacons among the Tunkers. Like the Quakers, they use great plainness of dress and language; they refuse to take oaths or to fight; they will not go to law, and until very recently, the receiving of interest for money was prohibited among them. They celebrate the Lord's Supper, and accompany it with love-feasts, washing of feet, the giving of the right hand of fellowship, and the kiss of charity. They anoint the sick with oil in order to their recovery, depending upon this unction and prayer, and rejecting the use of medicine. They generally believe in the doctrine of universal salvation; but it is not a tenet of the sect. They do not insist upon celibacy as an absolute rule; but they commend it as a virtue, and discourage marriage to the utmost degree possible. They are industrious and honest, and universally held in good repute among their neighbours.

Sole dependence upon prayer for the cure of the sick is the characteristic also of a small religious sect, of which a few members are to be found in England calling themselves the *Peculiar People*. A case was lately tried at one of the criminal courts in London, of parents belonging to this sect, accused of the manslaughter of their child, through neglecting to secure proper medical advice; and they were acquitted. In Switzerland, the name of Dorothea Trudel (d. 1862) was long famous for the cure of ailments by prayer. She did not, however, in all cases, refuse to call in medical advice. In Germany, a Protestant pastor, Blumhardt, pursues a similar system on a large scale, and it is said with great success. Cheerfulness, temperate habits, proper regulation of diet and exercise, various and interesting occupation of the mind, and frequent but not excessive introduction of religious reading, exhortation, and prayer, are the characteristics of his establishment, and there is much in them evidently favourable to the cure of many and especially incipient maladies both of mind and of body.

TUNSTALL, a prosperous market-town of England, in the county of Stafford, 5 miles north-west from Stoke-upon-Trent, with which it is connected by railway. T. has a good market-place and town-hall, several churches and schools; and in the vicinity, numerous collieries, potteries, chemical works, and veins of clay and iron ore. T. is included in the parliamentary borough of Stoke-upon-Trent, and the township has a pop. (1861) of 11,207.

TYLDESLEY, a well-built and increasing town of Lancashire, England, 10 miles west-north-west from Manchester, on a feeder of the Mersey. Cotton-spinning is extensively carried on, and there are numerous collieries in the neighbourhood. T. is a station on the railway from Manchester to Wigan. Pop. (1861) 3950.

TYNDALL, JOHN, physicist, was born in 1820, or thereabouts. His parentage was humble; but to the few educational advantages of his position, he brought an acute and active mind, whose early promise has been confirmed by the achievements of his riper years. On returning from the continent, where he received part of his education, he found employment in one of the subordinate grades of the Ordnance Survey. He was afterwards appointed Teacher of Natural Philosophy at Queenwood College, Stockbridge, and there commenced those original investigations which have distinguished him among the explorers of science.

In January 1853, T. communicated his first paper to the Royal Society *On Molecular Influences—Transmission of Heat through Organic Structures*.

It exhibits much of that skill in experimenting and fertility of resource which characterise his subsequent researches, and illustrates certain important questions in natural philosophy. The demonstration that wood is a bad conductor of heat across the fibre, and that the bark is a worse conductor than the wood, explains why trees are not killed by winter-frosts. And in the fact, that rock-crystal (pure silica) is a better conductor than some of the metals, we have a reason for the intense heat in the day, and rapid cooling at night, of the African deserts.

Year by year from the date above mentioned, T. has extended our knowledge of science. His field of research is wide and varied, as exemplified by the subjects of his papers published in the *Philosophical Transactions*—*On the Vibrations and Tones produced by the Contact of Bodies having Different Temperatures* (1854); *On the Physical Phenomena of Glaciers* (1857); *On some Physical Properties of Ice* (1858—1859); *On Transmission of Heat through Gaseous Bodies* (1859); a series on *Radiation*, six papers (1861—1865); *On Calorescence* (1865); *On the Invisible Radiation of the Electric Light* (1865). During the year 1867, he lectured on *Sounding and Sensitive Flames*.

In 1855, and again in 1861, T. was appointed to deliver the Bakerian Lecture to the Royal Society: the subjects were: *On the Nature of the Force by which Bodies are repelled from the Poles of a Magnet*; and *On the Absorption and Radiation of Heat by Gases and Vapours, and on the Physical Connection of Radiation, Absorption, and Conduction*, the latter being one of the series on *Radiation* above mentioned. The publication of this series of papers marks a period in the history of scientific research, for the facts therein set forth, and the conclusions drawn from them, demonstrate the relation of aqueous vapour to radiant heat, and elucidate certain meteorological phenomena which connect themselves with some of the profoundest and most interesting questions of cosmical science.

In 1864, the Council of the Royal Society awarded to T. their Rumford medal, in recognition of his scientific researches, particularly as bearing on Light and Heat.

As a lecturer on scientific subjects, T. enjoys a high reputation. His lectures at the Royal Institution and the School of Mines have been marked by fulness of knowledge and clearness of illustration. He has distinguished himself also as a traveller, particularly in the Alps.

In 1852, T. was elected a Fellow of the Royal Society, since when he has served twice on the Council. In 1853, he was appointed Professor of Natural Philosophy in the Royal Institution, where, as successor to Davy and Faraday, he sustains the reputation of the place for original scientific research. His lectures at the School of Mines have been attended by crowds of workmen. He is LL.D. of Cambridge, and is a member of a number of the scientific societies of the continent.

Besides his papers for the Royal Society, Professor T. has written articles in the *Philosophical Magazine* and other periodicals, among which may be instanced *The Fortnightly Review*. He has made himself known as an advanced thinker, fearless in the expression of opinion. His separate works comprise *The Glaciers of the Alps, being a Narrative of Excursions and Events* (1860); *Mountaineering in 1861* (1862); *Heat considered as a Mode of Motion* (2d ed., 1865); *Radiation*, being the Rede Lecture, delivered at Cambridge in 1865; *Lectures on Sound* (1867); and a biographical memoir of Professor Faraday (1868).

TYPE-SETTING MACHINES. Many ingenious inventions to set up type by machinery have been produced during the last twenty years in Great Britain, France, and the United States. Several were exhibited in the Paris Exposition of 1855, and in the London Exhibition of 1862. Almost all of these machines have been pronounced by practical men to be too complicated and expensive for general use. About twelve or fourteen years ago, Mr Robert Hattersley, of Manchester, turned his attention to this subject, and devoted many years to the construction of a machine for setting up type expeditiously, which should be easily manipulated, occupy little room, and be moderate in price. These objects Mr Hattersley has at length accomplished. After much labour, he has brought to perfection a machine which, for simplicity of action, is superior to any yet before the public. It stands on a space of 2 feet by 3, and is worked by touching a keyboard like that of a *concertina*. An intelligent operator, after a few weeks' practice, ought to be able to compose at the rate of from 4000 to 6000 types per hour, which is equivalent to the work of more than three men, setting up in the usual way. The type used is of the ordinary kind, not requiring to be cast on purpose, with certain 'nicks,' as is the case with the type used in some of these machines. The machine is fitted up with an extra *lower-case* supply-table, so that the operator never requires to be at a stand for want of fresh supplies of type. The price is £150. The same inventor has also perfected a machine for distributing type, as well as for arranging it for the composing process. The price of this auxiliary machine, which is an admirable specimen of ingenious inventive skill, is £90, and a still further saving of hand-labour will be effected by using it in connection with the composing-machine. Several of Mr Hattersley's composing-machines have already been introduced into newspaper offices in England; and strong certificates as to their satisfactory working, when *fairly* manipulated, are in possession of the inventor. They are, however, viewed with dislike by compositors belonging to the printers' unions; and employers, who shrink from encountering differences and disputes with their men, at present hesitate to introduce them. There is no limit to the speed with which these machines can be worked. All depends on the manipulative dexterity of the operator. The writer of this article has seen type put into the composing-stick attached to the machine at the rate of 25,000 per hour, by simply touching the *same key* successively with great rapidity; thus shewing that quick manipulation does not necessarily interfere with the accurate working of the machine. The writer has examined almost all the machines for type-setting yet exhibited, and is of opinion that Hattersley's is the most practical and useful. The only obstacle to the introduction of machinery of this kind will be the opposition of the unions, and the erroneous belief on the part of most compositors that it will interfere injuriously with their labour. In all cases where a variety of types is used, and display required in their arrangement—such as advertisements, circulars, hand-bills, title-pages, &c.—the machine would not be available, its use being limited to regular and plain setting only. When one considers the almost incredible strides made in printing, and compares the old-fashioned hand-press, producing only 100 impressions per hour, with Hoe's six, eight, and ten cylinder rotary machines, throwing off from 10,000 to 20,000 impressions per hour—and this power of production capable of still further multiplication by using duplicate and

triplicate stereotype *formes* on several machines—one cannot help believing that the art of setting up types is not likely to remain much longer as it is. At the present day, it is practically in nowise different from what it was in the time of Gutenberg, 400 years ago.

A purchaser of one of Mr Hattersley's composing-machines, after using it for ten months, states that it not only equals, but even exceeds the expectations he had formed of it. It is worked by a young girl, who in a day of nine hours is quite able to set up from 23,000 to 24,000 brevier types, as free from mistakes as the setting up of a first-rate compositor. He does not consider this amount of work at all equal to what the machine can produce in still more practised hands.

Another type-composing machine, containing 200 different letters, and suitable for all sizes of type, has lately been announced by Mr Mackie of Warrington, price £65. This machine, as far as the writer knows, has not yet been introduced into any office. The speed promised is at least double that of hand-setting. The same inventor announces a type-distributing machine, price £65.

TYRCONNEL, RICHARD TALBOT, DUKE AND EARL OF, born early in the 17th century. In his youth, according to Lord Macaulay, he was 'one of the most noted sharpers and bullies of London.' Soon after the Restoration, he endeavoured to obtain the favour of the royal family by blackening the reputation of Anne Hyde, so as to furnish the Duke of York with a pretext for breaking his promise of marriage to her. Though unsuccessful in this, he succeeded in gaining the favour of the duke, and contrived to make himself welcome at the palace both as a votary of its pleasures and as a counsellor in affairs of state. Immediately on the accession of James II., he was made Earl of T., and put in command of the troops in Ireland; and in 1687, by fawning, bullying, and bribing, he got possession of the office which had long been the object of his ambition—he was appointed Lord-deputy of Ireland. His arrival in that country spread terror and dismay through the English Protestant population, who had already suffered somewhat under his military rule. Events quickly justified their terrors. Nearly every office of dignity in the country was soon transferred to the hands of the Roman Catholics. The Protestant party, so long dominant, complained bitterly that they had become a laughing-stock even to their

own servants, and that to appeal to law was vain; judgment in every case being given for the native against the Englishman. But this state of matters did not last long. The revolution of 1688 had a sudden and sobering effect upon the rule of the Lord-deputy; and there can be little doubt that he would have submitted to William III.; but the Irish people threatened that if he dared to sell them for wealth or honour, they would burn the castle and him in it, and put themselves under the protection of France. On the arrival of James in Ireland in 1689, he created the earl, Duke of Tyrconnel. After the fatal battle of the Boyne, at which he held high command, he retired to France. In 1691, he returned to Ireland, with a view to furthering the efforts in favour of James, which were still being made by his adherents. Notwithstanding the defeat of Aghrim (12th July 1691), and the capitulation of Galway, he made preparations for the defence of Limerick, binding himself and his countrymen by an oath not to surrender until they received permission from James, then at Saint Germain. He at the same time despatched a letter in which he stated his conviction that all was lost. On the 11th August, before an answer could arrive, he was struck with apoplexy. He died on the 14th of the same month. He has been characterised by Macaulay as 'the fiercest and most uncompromising of all those who hated the religion and liberties of England.' He was survived until 1730 by his wife—'La belle Jennings' of the court of Charles II. This lady, so famed for her beauty and fascinating manner, entered life as maid of honour to the Duchess of York; in which position she conducted herself with a propriety which, time and place considered, may almost be pronounced unique. As wife of the Duke of T., during his rule in Dublin, her conduct seems to have been characterised both by dignity and purity. It is narrated that when James and her husband, fleeing from the defeat of the Boyne, reached her residence so bespattered with mud as to be scarcely recognisable, she dressed herself richly, and received the fugitive king and his attendants with all the splendour of court etiquette. She died in a small private nunnery in Dublin in circumstances of great poverty.—See Macaulay's *History of England*, vols. ii., iii., and iv.; Chambers's *Book of Days*, vol. i. ed. 1863, p. 310; Mrs Jameson's *Memoirs of Beauties of the Court of Charles II.*, vol. ii. p. 223.

U

UCA'ALI, a great river of South America, one of the chief headwaters of the Amazon. It joins the Amazon from the south, in S. lat. 4° 40', and W. long. 73° 30', opposite the town of Nauta in Ecuador; but the whole course of the river is in Peru. It is the largest river that joins the Amazon above the Brazilian territory, and on account of its length, has been regarded by some as the main stream of the Amazon, but at its mouth it is not above half the width of the Amazon. The Maranon and Huallaga from the south, with many smaller but still large rivers from the north, have united to

form the Amazon. The sources of the U. are in the Andes, Cuzco being situated on one of its feeders, which rises considerably further south; whilst another has its rise on the western side of the Andes, to the north-west of Lima, and after flowing southward for about 150 miles, makes its way through a cross valley, and takes a northward course. Attention has of late been very strongly directed to the U. as affording means of communication between the western parts of Peru and the Atlantic Ocean. It was partially explored by the Count de Castelnau and others in 1846, by Lieutenant Herndon and Mr Gibbon of the United States navy in 1851, and more recently by an expedition sent out by the Peruvian

government. It has been found to be navigable by steamers from its mouth to towns not far distant from Lima, 3700 miles from the mouth of the Amazon. On the branch which comes from Cuzco, there are falls and rapids, which form an impediment to navigation more than 100 miles below that city. The course of the U. is winding, but generally northward. Without regard to any but its principal windings, the length of its course is not less than 1100 miles. It receives many large branches. The name U. is not given to any of its head-waters, the chief of which is the Tambo, formed by the junction of Mantaro, the river which has its sources to the north-west of Lima, and the Apurimac, which comes from a more southern region. The greater part of the country through which the U. flows is covered with forest; but it seems very suitable for colonisation, if easy communication with the rest of the world were established, the soil being fertile, whilst the mountains abound in valuable minerals.

UMA'N, a town of Russia, in the government of Kiev, 120 miles south of the town of Kiev, on the Umanka. It is enclosed by earthen ramparts. Pop. (1863) 13,981.

UMBA'LLA, a large walled town of British India, Sirhind, 120 miles north-north-west of Delhi, on the Guggur. Under the walls of the fort is the encamping-ground of the British troops. Pop. 21,962.

UMRO'HAH, a town of British India, in the district of Moradabad, 80 miles east-north-east of Delhi. It is said to have a pop. of 72,677.

UNITED STATES OF AMERICA. During the year 1867, the United States made several important acquisitions of territory. In the beginning of that year, all the Russian possessions in America were handed over to the United States, upon payment of seven millions of dollars. The United States afterwards acquired Samana, on the north-east coast of San Domingo, with an excellent harbour, suitable for a naval station, from the Dominican Republic, for five millions of dollars. And in the latter part of the year, another transaction of the same kind was entered into (but not ratified), namely, to purchase from Denmark the islands of St Thomas and Santa Cruz. St Thomas (q. v.) is of great importance as containing the port first visited by steamers from England when they reach the West Indies, and from which other steamers start for different parts of that region. The town, however, is very unhealthy; several steamers have recently arrived in England with yellow fever on board; and on grounds entirely unconnected with the transference of the island to the United States, the question has begun to be entertained whether another West Indian station should not be sought instead of it, as the chief centre of commerce.—The country formerly Russian America is of great extent, comprising the whole north-western angle of the continent of North America, from the meridian of 141° W. long., with the peninsula of Alaska and its islands, and also extending southwards along the coast of the Pacific Ocean, from about lat. 60° N., where the meridian just mentioned meets the Pacific Ocean, for nearly 400 miles, to the northern border of British Columbia. This southern portion of the country is of various breadth, but nowhere extends much more than fifty miles from the coast, near which, however, are several large islands, one of them, Sitka, containing the principal town and port of the whole territory. See SITKA. The whole area of the territory is about 400,000 sq. m.; the pop. is estimated at

about 66,000. Since its transference to the United States, many Americans have settled at Sitka. The whole country enjoys a much milder climate than regions in the same latitude on the eastern coast of America. Magnificent forests cover great part of it. Even in the peninsula of Alaska, rain is more common in winter than snow. With its good soil, its pleasant climate, and its excellent harbours, this north-western portion of America seems likely soon to attract settlers, and to acquire great importance.

URICONIUM, an ancient Roman city of Britain, the site of which is about four miles to the east of Shrewsbury, and is partly occupied by the village of Wroxeter. The original name seems to have been *Viroconium*, which was changed in the later Roman-British period to *Uriconium*. It is mentioned by Ptolemy as existing in the beginning of the second century A.D. The remains of the city shew it to have been a place of much importance. The wall can still be traced near the banks of the Severn, forming an irregular oval rather more than three miles in circumference. It appears that one of the principal streets of the city occupied the line of the *Walling Street Road*. The remains of U. have recently been explored by an association formed for the purpose at Shrewsbury, and many curious relics of antiquity have been discovered, throwing great light on Roman civilisation in Britain. The human remains found in the excavations which have been made, affording proof of death by violence or by suffocation, shew that the city did not slowly decay, but was sacked and burned by enemies, which probably took place about the 5th century. Of this, however, there is no certain historic record. The ruins seem to have remained with little change, except the gradual process of decay, till about the 12th c., when they were used as materials for other buildings. Some of the churches of the neighbourhood were built of the old Roman bricks. The walls of buildings are now found, perfect as far as the previous accumulation of earth rendered it difficult to remove the bricks of which they were constructed. The most remarkable relic of antiquity in U. is the *Old Wall*, a great mass of Roman masonry, which appears to have been the side of a great edifice, remains of mosaic pavements having been found near it, and apparently connected with it. The edifice to which the Old Wall belonged is supposed to have occupied a corner at the junction of two principal streets. The excavations which have been made, however, leave it very difficult to explain the character and purpose of the remains discovered. Several inscriptions have been found at U., but none of great interest. A museum has been formed at Shrewsbury, in which most of the antiquities from this spot are collected. Hair-pins, combs, and rings are particularly numerous amongst them.

U'RINE, INCONTINENCE OF, or ENEURESIS, is a troublesome affection, far more common in childhood than in more advanced life. The child may have no bad symptom of any kind that can be detected, but it is in the constant habit of discharging its urine in bed during sleep. It sometimes wakes with a consciousness that it is performing the act, but most commonly it is not disturbed. The act may take place once, or several times, during the night, and sometimes there is an interval of a night, but seldom more. The child may often be broken of this unpleasant habit by proper domestic management, as withholding any excess of fluids before going to bed, and by waking it, and making it discharge the contents of the bladder at the time when the elder members of the family retire to bed. When such means as these fail, recourse must be

had to medical advice. Blisters to the sacrum, which prevent the patient from lying flat on the back, and consequently prevent the urine from gravitating towards the most irritable part of the bladder, are often useful; and cold douches to the spine, combined with the internal use of chalybeates, are frequently serviceable. The most certain remedy, however, is extract of belladonna,

given at first, according to the age of the patient, in doses varying from $\frac{1}{16}$ th to $\frac{1}{4}$ th of a grain, twice daily, and increasing it, if required, till it gives rise to marked constitutional disturbance.

The various forms of mechanical pressure that have been suggested, with the view of preventing the passage of the urine, cannot be too strongly reprobated.

V

VALENCIA, a town of South America, Venezuela, in the province of Caracas, 85 miles west-south-west of Caracas, about two miles east of a lake of the same name, and about 20 miles from Puerto Cabello on the coast, with which and with Caracas it carries on an active trade. V. is finely situated in an exceedingly fertile district, in which cattle and horses are raised in great numbers. Pop. said to be 16,000.

VALGUARNERA, a town of Sicily, in the province of Caltanissetta, 48 miles north-east of Girgenti, in a mountainous district. Pop. (1861) 9477.

VALLS, an old-fashioned town of Spain, in the province of Tarragona, in a plain watered by the Francoli, 55 miles west of Barcelona. V. is surrounded by ancient walls, has manufactures of cotton, woollen, silk, leather, and soap. The French, under St Cyr, defeated the Spanish here in 1809; but were in their turn defeated in 1811. Pop. 12,655.

VELLORE, a town and fort of British India, presidency of Madras, in the district of Arcot, 79 miles west of Madras, on the right bank of the Palar. The fort is extensive, is surrounded by a ditch cut in the solid rock, and contains barracks, hospitals, &c. The town is large, clean, and airy, and has an extensive and well-supplied bazaar. The town contains a most remarkable and splendid pagoda, dedicated to Krishna, whose adventures with the *gopis*, or milkmaids, are represented in a series of elaborate sculptures. Although the heat of V. is great, it is considered one of the healthiest stations in the Carnatic. V. was the residence of Tipoo Saib's family from 1799 to 1806, when they were removed on account of a sepoy mutiny, which resulted in a terrible massacre of Europeans. Pop. 51,500.

VERDEN, a walled town of Prussia, capital of a duchy, in Hanover, on the right bank of the Aller, here crossed by a bridge, and on the railway to Hanover, from which it is distant north-north-west 42 miles. Pop. (1864) 6037.

VERVICK, or **WERVICQ**, a town of Belgium, in the province of West Flanders, near the French frontier, on the Lys, 8 miles south-east of Ypres. Pop. (1863) 7220.

VIERSEN, a prosperous and beautiful manufacturing town of Rhenish Prussia, 18 miles west of Düsseldorf. V. has extensive manufactures of woollen and flax, as also of woollen, damask, silk and velvet stuffs, and ribbons; there are also dye-works and many other industries, which give

employment to thousands of workmen. The population of V. has more than doubled itself within the last few years, being in 1864, 15,129.

VIERZON-VILLE, an ancient and handsome town of France, in the dep. of Cher, 48 miles south of Orleans. V. has blast-furnaces, forges, and steel-refineries, manufactures of porcelain and earthenware, and a trade in cereals and wine. Pop. (1866) 8190.

VINAROZ, a town of Spain, in the province of Castellon de la Plana, on the coast of the Mediterranean, 83 miles north-north-east of Valencia. Ship-building is carried on, and there are active fisheries. The bay is open and unsafe. Pop. 9793.

VIRCHOW, **RUDOLF**, pathologist and publicist, was born in 1821 at Cöseln, in Pomerania. He was a pupil of the great physiologist, Johann Müller; graduated in medicine in 1843; and became, in 1847, prosecutor to the university of Berlin. The same year, he was commissioned by the government to investigate the cause and cure of typhus in Silesia; and also, in conjunction with Reinhardt, founded the *Annals of Pathological Anatomy and of Clinical Medicine*. The political commotions of 1848 dragged him, in common with many other votaries of science, into the revolutionary vortex. He established a journal entitled the *Medical Reformer*, and also a democratic club, where he soon distinguished himself as an orator. He was, in consequence, elected a member of the National Assembly, but was not admitted because he was, in a parliamentary sense, a minor. With the conservative reaction, V. had his journal suppressed, and lost his post, but was elected to the chair of Pathological Anatomy in Würzburg. His lectures at that university were widely popular for the novel views which he struck out, particularly in cellular pathology. His reputation grew so great that he was recalled by Manteuffel, in 1856, to Berlin, where he re-occupied the chair of Pathological Anatomy, and rendered it the most famous of its kind in Europe. In 1859, when the liberal cause revived, he became member of the municipal council of Berlin, where he distinguished himself as a reformer of the arbitrary police system then rampant; and soon after, was chosen deputy by the electoral college of Saarbrück, and by two of the Berlin colleges. He soon rose to the leadership of the Opposition, and proved a most effective antagonist of the encroachments made in the name of the royal prerogative. He took the lead, in January 1863, in carrying the address in which the ministry were accused of having violated the constitution. Such was the energy of his opposition, that in June 1865 he was challenged to a duel by

Count Bismarck. It must, however, be always understood that V. declines to be numbered with the radical party, but accepts the constitution, and only reserves the right of objecting to those measures which seem opposed to its spirit. His physiological and pathological writings are—his inaugural thesis, *De Rheumate Corneae* (1843); *Phlebitis, Thrombosis, Embolism, and Leucæmia* (1845—1847); *Typhoid Fever in Silesia* (1848); *The Colloid Tumours of the Ovaries, and on Cancer* (1847); *Cholera* (1848—1849); *Flexions of the Uterus, Scrofula, Tuberculosis, Typhoid Fever* (1850); *Cellular Pathology* (1850); *The Conjunctiva, &c.* (1851); *Amyloid Degeneration* (1853); *Collected Papers* (1856); *Cellular Pathology* (enlarged, 1858); *Morbus Spedalaka* (a disease peculiar to the Norwegian coasts, 1859); *Trichiniasis* (1860); *Tumours* (1862). He was elected Honorary Member of the Royal Medical Society of London in 1856, and in 1859, Corresponding Member of the Medical Society of Paris.

VIVIPAROUS FISH. It has been mentioned in the articles **FISHES** and **REPRODUCTION** that a few species of fishes are viviparous, or rather ovo-viviparous, the eggs being hatched within the ovary. An example of this occurs in the Viviparous Blenny of the British coasts. See **BLENNY**. But it is the common characteristic of a whole family of the order *Pharyngognathi*, therefore designated by the popular name of Viviparous Fish, and by the scientific name of *Embiotocidae*—a name formed from the Greek, and signifying *viviparous*. The general aspect of fishes of this family is somewhat perch-like; the scales are cycloid, the gill-covers are entire; the lips are thick. On the north-west coast of America from San Francisco to Sitka, species of this family are very abundant. They come into shallow water near the coasts, when the time approaches for producing their young, which is about the middle of summer. They swim in vast shoals close to the surface, and

have a peculiar habit of leaping high out of the water when alarmed, of which the Indians take advantage to capture them, by striking the water violently with their paddles, and uttering yells. The terrified fish leaping out of the water, many of them fall into the canoes. The Indians also capture these fishes by thrusting a spear with four barbed points into the midst of a dense shoal. They can be easily taken by nets, but are not of great value for the table. Our figure represents a

Viviparous Fish (*Ditrema argenteum*).
(From Lord's *Naturalist in Vancouver Island and British Columbia*.)

female, cut open to shew the manner in which the young are arranged within the mother.

VOU-CHANG, or WOO-CHANG, a city of China, in the province of Hoo-pe, on the Yang-tse-kiang, at the influx of the Han-kiang, about 350 miles south-west of Nanking. This is said to be one of the finest cities of China, famous for its learning and for its manufactures in metals. The pop. is stated at nearly 2,000,000.

W

WALSSEND, a parish of the county of Northumberland, England, four miles east-north-east from Newcastle, celebrated for its collieries, which produce a very large quantity of coal of very superior quality. About 2,000,000 tons of W. coal are annually imported into London.

WARREN, HENRY, president of the Institute of Painters in Water-colours, was born in London, September 24, 1798. W.'s father inherited considerable wealth, which, however, he contrived to dissipate, and his children were left to shift for themselves. The subject of this memoir at first got a situation in a counting-house; but afterwards, having an intense love for art, was placed in the studio of Nollekens, the celebrated sculptor of the day. At Nollekens's, he was associated with Bonomi and Gibson. Through Benjamin West, W. obtained an introduction to the sculpture-room of the British Museum, where he practised both drawing and modelling, and where he used to meet Haydon's pupils, Bewick,

Christmas, and the Landseers. In 1818, he became a student of the Royal Academy, where he attended regularly for many years in the company of Etty, the Landseers, F. R. Lee, Webster, and others less distinguished. W.'s first paintings were in oil. He exhibited several of these from time to time at the Academy. One was a subject from Collins's *Ode to the Passions*. Etty thought very highly of this picture, and W. repeated it in water-colour, and sent it for exhibition to the 'New Society of Painters in Water-colours,' of which he became a member at its foundation in 1835. Of this society, now known as the 'Institute of Painters in Water-colours,' W. has been president for the last thirty years, during which time, both by his teaching and example, he has done much towards raising the English school of water-colour drawing to the proud eminence that it now occupies in comparison with the same branch of art in foreign countries—namely, the highest place of all. W.'s first great picture in water-colours was 'The Happy Valley,' from *Rasselas*—a piece embodying both landscape and figures, and displaying great power both in its

composition and colouring. A great many of his subsequent pictures are on Eastern subjects, leading some persons to suppose that he has lived a long time, or at least travelled much, in Egypt, the Holy Land, Arabia, &c. But this is not the case. Among these Eastern subjects, many are Scriptural, as—'Rebecca at the Well,' 'Hagar and Ishmael cast out into the Wilderness,' 'Christ and the Woman of Samaria,' 'Joseph's Coat brought to Jacob,' 'Christ with his Disciples in the Cornfield,' 'The Death of the First-born,' 'The Flight into Egypt.' Of eastern subjects not scriptural may be named—'The Dying Camel in the Desert,' well known by the engraving so deservedly popular; 'A Halt in the Nubian Desert;' 'Mosaic Charity;' 'The Crusaders' First Sight of Jerusalem;' and 'The First Sunset witnessed by our First Parents.' This picture, with its beautiful landscape and admirably drawn figures, is said by a good authority to be 'worthy of being classed with the best works of John Martin and Danby.' Of subjects not Eastern there may be mentioned—'Alfred in the Swineherd's Cottage,' 'The Warrant exhibited to the Lady Abbess of a Benedictine Nunnery for the Suppression of her Convent,' 'Incipient Courtship,' 'Happy Nutting Days,' &c., besides numerous English landscapes done from nature with much feeling and truthfulness. W. is an honorary member of the 'Société Belge des Aquarellistes,' and of the 'Pennsylvanian Academy of Arts;' he is also Professor of the Fine Arts at Queen's College, London. He was one of the Committees of Selection in the Fine Arts Department for the Great International Exhibition at Paris in 1855; again for that of London in 1862; and for that of Paris again in 1867. W. has written a little book on *Artistic Anatomy*, which has gone through many editions; also a book on *Water-colour Painting*; two funny books, *Notes upon Notes*, and *Hints upon Hints*; and an antiquarian work, *On the River Ravensbourne*. In 1829, W. was married to Isabella, niece of John Martin the painter, and has a son, Edmund George, also a water-colour artist, whose drawings of landscape—especially when he deals with woodland scenery—have, by their originality and truthfulness, placed their author in the foremost rank of landscape painters.

WAR-SERVICES. The science of destruction has made such rapid progress during the years in which this *Encyclopædia* has been in course of publication, and so many changes have taken place in the *personnel* and *matériel* of the armies of all the great powers, that to render the more important descriptive articles complete, it is necessary to add a few words to bring their information down to the standard of 1868. The articles most requiring supplement are the following, in their alphabetical order:

ADMINISTRATION, MILITARY.—This is the comprehensive title for all that complicated machinery by which the military force and energy of a nation are endowed with cohesion and vitality. The expression Staff (q. v.) applies in a somewhat similar sense to the governing and ministering centre of a specific army, but is as much inferior to the general Military Administration as a single army is less than the country's aggregate military strength. In every nation the head of the whole administration is the minister of war, whatever exact title he may bear. Under him are the great officers charged with superintending the discipline, payment, and supplies of the army or its parts wherever situated; the military manufactures, and the national reserves. It is not necessary here to specify the various sub-departments under these chief officers; but there is at head-quarters a section representing each civil

department serving with the army, and charged with the duty of directing and supplying that department with all things required to maintain its efficiency.

ADMIRAL.—The distinction of flag—red, white, or blue—has been abolished, and the flag-officers now constitute three classes only—viz., admirals, vice-admirals, and rear-admirals, all carrying the white ensign and pendant, and the St George's cross on a white ground as their distinguishing flag, hoisted according to rank at the main, fore, or mizzen mast-head respectively.

AMBULANCE CORPS.—The functions of this body of men are at present undertaken by the Army Hospital Corps in the British army.—In the French army, the duty is confided to a section, specially trained, of the *Train des Equipages Militaires*.

ARTILLERY, ROYAL REGIMENT OF.—The terms Battalion, Company, and Troop have been abolished, in favour of Brigade and Battery, which apply both to horse and foot artillery. The regiment now consists of 33,500 men, thus distributed:

| | | | |
|----|---|------------------------------------|------------|
| 6 | brigades of horse artillery, comprising | 30 | batteries. |
| 8 | " | field (foot) artillery, | " 62 " |
| 14 | " | garrison (foot) artillery, | " 103 " |
| 3 | " | mixed (foot) artillery, | " 19 " |
| | | | 214 |
| 1 | " | coast artillery, not in batteries. | |
| 1 | " | dépôt artillery, | " " |
| 33 | | | |

This force represents from 1200 to 1300 guns fully equipped for action. Of the foot artillery, the garrison batteries are readily converted to field-batteries by the addition of a few drivers.

BALLISTIC PENDULUM.—The use of this apparatus as a test of the initial velocity of projectiles has nearly ceased, its place having been taken by the Electro-ballistic Apparatus of Major Navez, a distinguished Belgian officer. This apparatus consists of a pendulum moving on a graduated arc of a circle, at a known velocity, at the top of which it is held by an electro-magnet. The projectile is fired through two screens at a known distance apart. In passing through the first screen, it breaks the electric circle, and demagnetises the magnet, causing the pendulum to fall. As the ball passes the next screen, it restores the circuit and the magnetic power, instantly arresting the pendulum in its downward course. The portion of the circle passed over by the pendulum shews the time occupied by the ball in passing from screen to screen; and that distance being known, the initial velocity becomes a question of very simple calculation. Of course, the magnet and the two screens are connected by wires with a voltaic battery.

BARRACKS.—The office of Barrack-master-general had been abolished in 1822, and the duties transferred to the Board of Ordnance. On the extinction of that Board in 1855, barracks came under the control of the Secretary of State for War, who confides the executive to two departments of his office—the Director of Works in regard to buildings and lands, and the Superintendent of the Barrack Department in regard to the personnel. The system of government has been so far altered since the article BARRACKS was written, that all the barrack-masters in any military district are supervised by one of their number, who ranks as district barrack-master. The correspondence of the whole district with the War Office is conducted through this officer. Barrack-masters have been granted relative rank and increased pay, with some other minor advantages.

BOOTY.—A very important decision was given by Dr Lushington, judge of the Court of Admiralty, in 1866, on the subject of the degree of co-operation

WAR-SERVICES.

which entitled combatants to share in booty. The case arose on the question of the Banda and Kirwee prize-money, captured in 1857—1858 by the Central India Field-force; and, speaking broadly, the decision was that only those divisions of an army could share the booty which were either directly concerned in its capture, or contributing to that operation by co-ordinate fighting within a reasonable distance of the principals. This excludes those portions of the army which inferentially contribute by keeping the enemy employed in other theatres of war. The commander-in-chief of the whole army, with his general and personal staff, take a share as well as the staff immediately in command of the capturing division. In the case in point, the capture was made in Central India, and the divisions at Delhi, the Punjab, and Oude were held to be excluded.

BREVET.—General promotion by brevet has for many years been abolished in the navy, and in 1854 was abolished for the army. Brevet rank can at present be obtained in three ways only, and never extends above the grade of colonel. Captains or majors may receive brevet promotion for distinguished service before the enemy. Lieutenant-colonels have brevet promotion to colonel, after commanding battalions or holding certain staff appointments for five years. When a general officer dies, the senior major and captain in the army receive each a step of brevet rank. Surgeons of twenty years' total service (or of less service for distinguished conduct) receive brevet rank as surgeons-major. These are the only modes in which brevet rank can be obtained. In the United States army, however, brevet rank is given in any grade; and we find officers with the puzzling title of 'Brevet-major-general.'

BRITISH NAVY.—In 1859, the navy was made a steam-navy, and sailing-vessels of war ceased, practically, to exist. No sooner was this accomplished, at great expense, than, at a still more enormous outlay, it was found necessary again to reconstruct the navy by building vessels more or less encased in iron plates, varying in thickness from 4½ to 7 inches. There were in 1867 thirty-four iron-cased ships in the British navy, of which the *Minotaur* and *Northumberland* were the largest war-ships in the world. Monitors or turret-vessels are being added, but to this time, rather as experiments than effectives.

CANNON.—The following table now shews the qualities of ordnance in use in the British army and navy:

BRECHT-LOADING RIFLED GUNS.

| Name. | Calibre. | Length. | Weight. | | |
|-----------------------|----------|---------|---------|------|----|
| | | | Tons. | Cwt. | |
| 7-inch, | 7 | 10 | 0 | 4 | 2 |
| 7 " " " " " " " " | 7 | 9 | 11 | 3 | 12 |
| 64-pounder, | 6·4 | 8 | 2 | 3 | 1 |
| 40 " " " " " " " " | 4·75 | 8 | 2 | 1 | 12 |
| 20 " " " " " " " " | 3·75 | 6 | 6 | 0 | 16 |
| 12 " " " " " " " " | 3 | 6 | 0 | 6 | 2 |
| 9 " " " " " " " " | 3 | 5 | 2 | 0 | 6 |
| 6 " " " " " " " " | 3·5 | 5 | 0 | 3 | 3 |

MUSKET-LOADING RIFLED GUNS.

| | | | | | |
|-----------------------|-----|----|----|----|---|
| 12-inch, | 13 | 14 | 2 | 23 | 0 |
| 9 " " " " " " " " | 9 | 12 | 3 | 12 | 0 |
| 8 " " " " " " " " | 8 | 11 | 4 | 9 | 0 |
| 7 " " " " " " " " | 7 | 11 | 10 | 7 | 0 |
| 64-pounder, | 6·3 | 9 | 3 | 3 | 4 |

SMOOTH-BORE WROUGHT-IRON MUSKET-LOADERS.

| | | | | | |
|------------------------|------|----|---|----|---|
| 150-pounder, | 10·5 | 12 | 3 | 12 | 0 |
| 100 " " " " " " " " | 9 | 10 | 3 | 6 | 5 |

In addition to the above, there are in all fortresses and in many ships numbers of the old cast-

iron ordnance, for which the new guns are in course of substitution.

CANNON-FOUNDING.—Guns, whether of iron or brass, have ceased to be cast at Woolwich. All new guns are now formed of iron or steel bars, wound while red-hot into a coil round a mandril, and welded together into a solid barrel. Such a coil never bursts explosively.

CLOTHING, ARMY.—All uniforms are now issued to the soldier without charge against him. It is merely for the renewal of 'necessaries' that the price is debited against him, the price being precisely the wholesale cost to government, and far less than that at which the soldier could purchase it.

COAST-GUARD has been organised under the chief direction of a comptroller, who has the rank of commodore, and is at the head of a department at the Admiralty.

COLONEL.—The colonelcy of a regiment is always held, as a sinecure, by a general officer, who receives £1000 a year in line regiments, and somewhat higher pay in the Guards, the best appointment being to the Grenadier Guards at £2200 a year. The rank of colonel, when held by an officer who is not a general officer, is always, except in the artillery and engineers, brevet or army rank, carrying no regimental function or precedence with it.

COLONIAL CORPS.—Of those mentioned in the original article, the following have been disbanded: Newfoundland Veterans, Ceylon Invalids, St Helena Regiment, Gold Coast Artillery, Falkland Islands Company. On the other hand, a fourth West India Regiment has been added; and a second battalion of the Ceylon Rifles is in course of formation for service in the Straits Settlements and in Hong-kong. The Malta Fencibles have been converted into a corps of artillery, and are highly efficient. The total strength of the colonial corps is about 8000 men of all ranks.

COMMISSIONS, ARMY.—The prices of cavalry commissions have been assimilated to those of the infantry. In the Foot Guards, commissions are not saleable above the rank of 'captain and lieutenant-colonel.'

CONTROL DEPARTMENT—sometimes called the **COMPTROL DEPARTMENT**—a presiding civil department of the army, the creation of which has furnished ground for much public controversy throughout 1867, and for much misapprehension since the appointment of a controller-in-chief to the War-office in January 1868. The common idea seems to be, that this officer, who holds high rank in the military hierarchy, is to control the whole War-office, and consequently the Minister of War himself. His title is not a very felicitous one; but his functions are merely to control the departments charged with army supplies, that is, the Commissariat, Store, Purveyors, Transport, and Barrack departments. The appointment is the result of an inquiry in 1866 and 1867 by a committee of officers, of whom Lord Strathnairn was chairman. The recommendation was, that the departments specified should not only be concentrated at head-quarters; but that in every command there should be a controller, or deputy or assistant controller, according to the importance of the charge, whose duty it should be to harmonise the same departments within the command. It is the corporation formed by the controller-in-chief and these local controllers which will constitute the Control Department. The actual department has not as yet been formed, but it is understood that the year 1868 will not expire without its completion.

CROSS, VICTORIA.—This distinction is also applicable to the navy.

DEPÔTS.—There are as many depôts as there are regiments abroad, the depôts being, for the sake of battalion training, formed into depôt battalions, which are virtually regiments. The head-quarters are not at the depôt, but with the service companies; and when a regiment returns from foreign service, the depôt joins the service companies.

DOCKYARD BATTALIONS no longer exist, with the exception of a small corps at Malta.

ENLISTMENT, ARMY.—By an act of 1867, the first period is fixed at 12 years, and the second at 9 years, for all arms of the service. Men are also empowered and encouraged to enlist for general service, as distinguished from enlisting for particular regiments.

ENSIGN.—The use of the white ensign is now peculiar to the British navy; the red ensign being assigned to yacht-clubs and non-combatant government vessels; and the blue ensign to vessels of the merchant service.

FIFER.—A fifer now receives pay at 1s. 2d. a day; and a fife-major, 2s. 4d.

FLEETWOOD.—The School of Musketry at this port has been discontinued.

GUN-CARRIAGES.—In consequence of the great weight of modern artillery, and the enormous strain produced by its discharge, it has been found cheaper and more efficient to construct carriages of wrought iron for all naval and garrison guns of or exceeding 6½ tons in weight.

GUN FACTORIES, ROYAL.—The establishment of Sir William Armstrong & Co. at Elswick, has ceased to be connected with government. When, in 1863, the government work was withdrawn, a sum of £85,000 was paid to the Company as compensation for the plant, &c. they had set up for the purposes of the manufacture.

LAUNCH (boat).—The launches of the largest ships of war are now usually decked vessels, fitted with steam-engines, and capable of cruising and fighting on their own account. They are hoisted inboard when the ship is on her course.

MUSKETRY, SCHOOLS OF.—The school at Fleetwood has been discontinued, duplicate establishments being found an unnecessary expense.

PALLISER GUNS AND PROJECTILES.—Since the issue of that portion of the *Encyclopædia* devoted to great guns, a considerable step in advance has been taken under the auspices of Major Palliser, a cavalry officer on half-pay. His guns have resisted charges that would have instantly shattered any others yet brought forward; and by the aid of his hardened projectiles, shields have been pierced which had defied the heaviest bolts of all other ordnance. Although only prominently before the public during the last three or four years, this indefatigable officer has been experimenting from time to time since 1854, always in the one direction, which has resulted in forming the gun which will in all probability be that adopted by all governments. Cavalry service in the Crimea and in India interrupted the investigations, but they were always resumed the moment opportunity offered. The principle of Major Palliser's gun is readily understood.

With the large charges used in this country, cast-iron guns were unequal to projecting modern shot and shell, and wrought-iron ordnance were introduced. These answered their purpose to a certain extent, as in the Armstrong and other guns; but there was an element of uncertainty in their texture, and some of them had burst with bad effects. To this might be added their enormous expense; and the fact that thousands of large cast-iron guns were in store, to all appearance useless. Many attempts have therefore been made to utilise these cast-iron guns, the means adopted being generally

to shrink rings of wrought iron over them. This has not proved effectual, and the guns have become preposterously cumbrous. Next, the cast-iron guns were bored up to a greater calibre, and then a thinner cannon (called a tube) was inserted, this tube being a cylinder of wrought iron or steel bored to the proper calibre. The strength thus added to the gun has been but little. Major Palliser's system for converting guns is to insert a tube of wrought iron; but that tube is *coiled*, as in an Armstrong gun, by winding a bar of iron round a mandril, and then welding it into a continuous barrel. These guns have withstood the utmost strain brought to bear upon them. For the preferable and cheaper process of making new guns, the iron would be cast in the ordinary way around the wrought-iron tube. For the purposes of this tube, Major Palliser finds the softest and most ductile wrought iron the best, having a certain stretch in it. The authorities had already found out that thick iron plates could not be penetrated except by steel projectiles; but their use was greatly limited by their great cost. Major Palliser came, by experiment, to the conclusion, that toughness was not a necessary feature in the shot, and that hardness—no matter how brittle the material might be—was the real thing necessary for extreme penetration. With this view, he selected white iron, and cast it in *chill*, which secures the requisite amount of brittle hardness. To cast in chill, an iron mould of the exact shape is employed, with raised studs of sand inside it. The liquid metal is poured in (the sand studs forming holes for the studs of the future shot or shell to be fixed in); and the rapid conduction of heat by the iron mould causes so sudden a cooling from the outside of the mass, that the particles of iron are driven closer together than in their normal state. This produces intense hardness. The same inventor has ascertained the proper shape for the head of a shot or shell, as opposed to the flat head, the pointed conical head, and the hemispherical head already in use. He determined that the form of greatest power is the *conoidal*, which lies between the conical and the hemispherical, the conoid consisting of the intersection of two circles, each with a radius equal to twice the diameter of the projectile.

RECRUITING.—The competition of the labour-market at home and abroad telling very disadvantageously against the recruiting-sergeant, a Royal Commission was appointed in 1866 to consider by what means the evil might be lessened. Although all the recommendations of the commission have not been adopted, several have taken effect. Among others, an Inspector-general has been appointed to superintend and harmonise all the recruiting operations; to render the conditions of service more attractive, the pay of every soldier has been increased twopence a day, with an additional penny in prospect, if he continue to serve after the expiration of his first period of service. It is, however, to be observed that this result caused general disappointment, there being no broad views propounded by which to render recruiting for the army less difficult.

RESERVE FORCES OF THE UNITED KINGDOM.—By two acts of 1867—one for an 'Army Reserve' of 50,000 men, and the other for a 'Militia Reserve' not exceeding one-fourth the number of militia—power has been given to organise a more effective body of trained men of previous good service in the army or militia, who shall be immediately available in case of invasion or imminent danger, for being drafted for the period of danger into the regular army. It is understood to be in contemplation to allow soldiers to commute their last five years of army

service into a double period in the Army Reserve, which would leave them at liberty, under restrictions, for civil employment, without depriving the country in any exigency of their services as soldiers. With a view to harmonise the several constituents of the Reserve, and to give them that corporate organisation which is still wanting, a high officer, the Inspector-General of Reserve Forces, has (April 1868) been appointed at the War-office.

There is a growing feeling throughout the country, as well expressed in 1867 by Lord Elcho in the House of Commons, that every citizen should be ready to bear arms in defensive war; and that, with this view, every young man should serve for two years or some other short period with the army on home service. That such a measure would raise the character of the army, while it diminished the cost of recruiting, it is impossible to doubt; how far this system and the purchase of commissions would be compatible, may be more doubtful.

RIFLED ARMS.—Adverting here simply to the system adopted for rifling—whether by grooves or otherwise—the bore of the gun or rifle, and irrespective of the construction of the arm in other particulars, the scientific inquiries of the government may be said to have been brought to a close.

In small-arms, the competition has lain between the Enfield, Lancaster, and Whitworth systems. Of these, taking all considerations into account, it is held that the Enfield system is incomparably the worst; and the Lancaster system of oval bore the best. If a new rifle be adopted for the army, when the converted Sniders shall be worn out, it is probable that the Lancaster bore will be employed.

In great guns, after protracted experiments with the systems which gave the most favourable prospects—viz., those of Armstrong, Whitworth, Lancaster, Scott, and the French rifling—it has been decided to give the preference to the French plan, with the exception that the grooves are wider and shallower. All rifled cannon now made in the Royal Arsenal are constructed on this system, which is called the 'Woolwich' system, with a variable number of grooves according to the calibre of the piece.

RODMAN GUN.—This has been extensively used for large ordnance (smooth bore) in America, and is said to stand heavy charges. The guns are of cast iron, cast hollow, and then cooled from within, the process producing great hardness round the bore. A 16-inch gun was tried in 1867 at Shoeburyness; but the results, though on the whole not unfavourable, were scarcely such as would lead to its introduction in the British service. It has been suggested that a Rodman gun lined with wrought iron on Palliser's system, would prove a highly effective weapon.

WATLING STREET, one of the great Roman highways of Britain, commencing at Dover, passing through Canterbury and Rochester to London, and thence through Uriconium and Chester to Caer-Seiont, the ancient *Segontium*, in Caernarvonshire. From Uriconium, a branch proceeded north by Manchester, Lancaster, and Kendal, into Scotland. Traces of the ancient road are still to be found in many parts of its course, and in some it is still an important highway. A street in London retains its name. The origin of this name is very uncertain; the most probable supposition is that the original name was *Stratum Vitellianum*.

WATTS, THOMAS, a distinguished philologist and librarian, was born in London early in the present

century. At school he studied Latin and French, and in due time Greek as well; but he principally distinguished himself by his attainments in English. He read every book that came in his way, and he wrote, apparently with the utmost ease, tales, essays, and poetry, very much above the average, not alone of school-boy composition, but of the magazine-writing of the day. To a knowledge of the classics and French, W. soon added an acquaintance with the other languages of the Latin family—as Italian, Spanish, and Portuguese; likewise with the German, Dutch, Swedish, Danish, and Icelandic. The facility with which he acquired these several languages, encouraged him to undertake, from time to time, the study of some of the oriental tongues, viz., Hebrew, Arabic, Persian, Turkish, and even Chinese. In each of these he made considerable progress, but cannot be said to have mastered any of them as he did those languages before named, and as he subsequently mastered the Russian, Polish, and Hungarian. There are few Englishmen who know anything of the three languages last named, which W. could read and translate with the utmost ease—being as familiar, in fact, with their great writers as he was with those of Germany or France. It remains only to mention that W. was also well acquainted with the Welsh language and literature, besides having some knowledge of the Gaelic and Irish as well. Upwards of 20 languages have thus been named with which he was well acquainted. No other Englishman has approached him as a linguist, considering the *variety* as well as the *number* of languages which he acquired; while of foreigners, it is not too much to say that Mezzofanti alone appears to have surpassed him.

In 1832, W. first became a 'reader' in the Reading-room of the British Museum, where, in studying some of the languages mentioned, he became acquainted with the deficiencies in the literature of other countries under which our national library then laboured. In 1837, the Rev. Mr. Baber, then keeper of the Printed Books, purchased, at his recommendation, a small collection of Russian books, which W. offered to catalogue as a volunteer. This brought him the acquaintance of Mr. Panizzi, who, becoming aware of his attainments, recommended him for employment in the library. Accordingly, he was engaged as an assistant in the department of Printed Books, January 1838. At that time, the books were being transferred from the old rooms in Montague House to the new library. It was W.'s duty to assist in the rearrangement of the books, and when this was finished, he was intrusted with the responsible duty of arranging and placing on their shelves, according to subjects, all the new works purchased or otherwise acquired for the library. For this his vast acquirements as a linguist eminently qualified him. In other respects also his knowledge of languages was brought to bear in the service of the Museum. He drew up lists of desiderata in all the languages of Europe. It was at his suggestion also that the first large orders were given for American books. 'The object' (says W. in a letter to the principal librarian in 1861, printed by order of the House of Commons in 1866) 'which has been kept in view during the last three-and-twenty years has been to bring together from all quarters the useful, the elegant, and the curious literature of every language; to unite with the best English library in England or the world the best Russian library out of Russia, the best German out of Germany, the best Spanish out of Spain, and so for every language from Italian to Icelandic, from Polish to Portuguese. In five of the languages in which it now claims this species of supremacy, in

Russian, Polish, Hungarian, Danish, and Swedish, I believe I may say that, with the exception of perhaps fifty volumes, every book that has been purchased by the Museum within the last three-and-twenty years has been purchased at my suggestion. I have the pleasure of reflecting that every future student of the less known literatures of Europe will find riches where I found poverty.' The number of books classified and arranged by W., while only an assistant in the library, is reckoned at about 400,000 volumes, and of these as many as 100,000 were arranged upon a plan of his own invention, now known as 'the elastic system.' 'One of the advantages,' he says, in the letter before mentioned, 'obtained by this system is, that when the new library, which surrounds the new Reading-room, was ready for the reception of books, these 100,000 volumes were removed to their new locality without the necessity of altering a single press-mark: had the operation of altering the press-marks been still required, as under the former system, the amount of labour necessary to effect it would have been enormous, and the expense not less than some thousands of pounds.' Here it may be mentioned that it was W. who first suggested the erection of a library and large reading-room in the vacant quadrangle, where now rises the splendid dome erected under the auspices of Panizzi. The suggestion was originally made in a series of articles contributed anonymously to the *Mechanics Magazine* for 1836 and 1837, since that time acknowledged by W. as his own. In one of these, speaking of the quadrangle, he says: 'The space thus unfortunately wasted would have provided accommodation for the whole library. A reading-room of ample dimensions might have stood in the centre, and been surrounded on all four sides by galleries for the books, communicating with each other, and lighted from the top.' In 1856, W. was promoted to be assistant-keeper of the Printed Books; and on the opening of the splendid new Reading-room in 1857, he was most fitly appointed its superintendent. In August 1866, W. was appointed keeper of the department of Printed Books. He died in September 1869. W. was a member of the Philological Society of London; he was also an honorary member of the Hungarian Academy, to which he was elected at the same time as the late Lord Macaulay. Among the literary productions of W. may be mentioned: 'Notes of a Reader,' contributed to a weekly periodical entitled *The Spirit of Literature*, 1830; numerous poetical pieces contributed to Linnington's *Rhetorical Speaker and Poetical Class-Book*, 1833; *A Letter to Antonio Panizzi, Esq., on the reputed Earliest Printed Newspaper*, 'The English Mercurie, 1588,' 1839; *A Sketch of the History of the Welsh Language and Literature* (reprinted from Knight's *English Cyclopædia*), 1839; more than a hundred biographies of eminent men, Russian, Hungarian, Bohemian, &c., contributed to the same *Cyclopædia*; numerous articles in the *Biographical Dictionary* of the Society for the Diffusion of Useful Knowledge; papers in the *Transactions of the Philological Society*, among which are an 'Essay on the Hungarian Language,' and a biographical notice of Cardinal Mezzofanti; also contributions to the *Quarterly Review*, the *Athenæum*, and other literary periodicals.

WEAVING. There is no branch of manufacture in which inventions and improvements are more rapidly succeeding each other than in weaving; but, as a rule, they are of minor importance, and rarely affect the general principles of the process. In 1867, however, the novelty of *Convex* weaving by machinery was introduced, and although only at present applied to ladies' stays, seems to promise a

wide application to clothing generally, and many other purposes.

Out of the numerous attempts that have been made during the last ten years to weave by machinery a convex surface, such as is required in several articles of clothing, hardly one, up to the present time, has succeeded. This failure has been owing partly to deficiencies in the various inventions of this kind, and partly to the costliness of carrying them out. At last, after long and patient trials, a patent convex weaving-loom has been invented that not only answers all the purposes of the hand-loom, hitherto exclusively used, but also possesses the advantage, which is absolutely necessary in a country where labour is scarce, of doing ten times the amount of work in the same space of time. With the hand-loom, one man can make, at the very utmost, only four pair of stays in a day, whereas the new-invented convex weaving-machine turns out 40 pair daily. The superior lightness and flexibility of woven stays, and their perfect freedom from hard seams, have increased to a very large extent the demand for this class of goods. Up to the present moment, hand-labour alone has been employed in France and Württemberg, two countries where they have been most extensively manufactured. In the United States, however, where the high wages for hand-labour have necessitated the most extensive use of machinery, this system could not be adopted with any possibility of pecuniary success; and, in consequence of this fact, a loom for weaving of stays and other convex goods had to be invented. This loom, which was constructed under the superintendence of M. Opper, for the Convex Weaving Company in New York, does the work automatically and to perfection.

The principle of a constant length of travel for the shuttle was adopted for the sake of simplicity; but, as it is necessary, in weaving the goes, that the weft-thread should pass through only a part of the breadth of the warp, the Jacquard has been employed for the purpose of taking up the portion of the warp required to be woven in that part. It is impossible by mere verbal description to give any adequate notion of this ingenious machine without seeing it in operation.

WEIR, or WEAR—called also a dam, and in the north of England and south of Scotland, a cauld—a structure placed across a river or stream, for the purpose either of diverting the water into a mill-lade, of raising the level of the surface of the river, and thereby increasing its depth for the purpose of navigation, or of providing the means of catching salmon and other fish. There is also the waste-weir, for the purpose of preventing a reservoir embankment being overtopped by floods; and the gauge-weir, for the purpose of computing the quantity of water flowing over it, from a measurement of the difference of level between the crest of the weir and the surface of the still water above it. The word is also sometimes used, though perhaps not quite correctly, to denote a training-wall or other structure parallel with the general line of a river, for the purpose of remedying or preventing loops or sinuosities. A weir may—according to the purpose for which it is intended, to the nature of the materials at command, or to other circumstances—be formed either of stone, timber, or brush-wood, or a combination of any two. It is generally placed obliquely across the stream, in order to make the length of its crest considerably greater than the width of the channel (fig. 1), and thereby prevent the water in floods from rising to so great a height as it would do with a shorter crest, to the risk of damaging the adjoining low lands, and probably putting the mills above in backwater. In

WEIR.

such cases, the mill intake, or the navigation lock, as the case may be, is generally placed at the down-stream end of the weir. Much obliquity, however,

Fig. 1.
A, intake.

makes the current to impinge against and to cut into the side of the river opposite the lower face of the weir, and to prevent that effect, weirs are sometimes made of the shape of two sides of a triangle, or rather of that of a hyperbola, with its apex pointing up stream, which arrangement is peculiarly applicable to the case of there being an intake for a mill on each side of the river (fig. 2), and the apex is a

Fig. 2.
A, A, intakes; B, fish-pass.

very suitable place for a fish-pass or ladder. Not unfrequently, when at a wide part of the river, the weir is placed at right angles across, and with a slight curve upwards (fig. 3); and a natural shelf of

Fig. 3.
A, intake.

rock is often very advantageously made use of for either a mill or fishing weir, the low parts being made up where necessary with stone or timber.

The down-stream face of a weir is generally a pretty flat slope of stone 'pitched' or set on edge, and with its toe, or lower edge, either sunk into rock, or protected from being underwashed by a row of timber-sheeting piles, and frequently also by an apron of timber-planking. This slope is either straight, or made with a hollow curve (fig. 4), so as to check the tendency of the water to acquire increasing velocity as it descends; and it is frequently divided into panels by timber-framing, so as, in the event of a portion of the pitching being

washed out, to lessen the risk of the whole of it being carried away. The up-stream face is generally a slope dipping into the water, and protected by

Fig. 4.
A, masonry; B, pitching; C, clay puddle.

stone pitching, but it is sometimes a perpendicular wall. In order to render an ordinary sloping weir water-tight, sometimes there is under the crest or coping a row of well-jointed and close-driven timber sheeting-piles; but those being liable to decay, without their decay being visible, a better, though a more difficult and expensive arrangement, is to build a perpendicular wall of water-tight masonry under the crest. In either case, generally there is the additional precaution taken of having a wall of pounded clay on the up-stream side of the wooden or stone barrier; and sometimes a mere wall of pounded clay alone, in the centre of the weir, is trusted to, as the sole means of making it water-tight; but the latter is not a satisfactory arrangement, unless the stone-work next to the clay be so closely compacted by an admixture of gravel and sand as to prevent any current of water from reaching the clay, and cutting into it. The down-stream face is sometimes made a nearly perpendicular wall, which, unless for the obstacle which it presents to the ascent of the salmon, is a very good arrangement, where the bottom of the channel is solid rock, so as not to be liable to be scooped out by the falling water; else it must have at its foot a level apron of heavy masonry for the water to fall on (fig. 5).

Fig. 5.
A, masonry; B, pitching; C, clay puddle.

The down-stream face is also sometimes made of a series of steps, so forming a succession of levels and light falls (fig. 6), which is a very good plan for

Fig. 6.
A, masonry; B, pitching; C, clay puddle.

breaking the force of the falling water; but it, like the perpendicular face, presents obstacles to the ascent of the salmon, unless a fish-pass or ladder be provided.

The weir for the purpose of navigation need not be in any way different from the mill-weir, otherwise than that, instead of an intake sluice, there

must be a Lock (q. v.) with upper and lower gates, and a chamber between them as long and as wide as the largest vessels navigating the river. Fishing-weirs are generally provided with a sort of cage,

Fig. 7.

A, heck; B, B, inscales.

and three inches apart, so as to let small fish get through, and at the lower end two folding horizontally sparred doors called the inscales, pointing upwards, but set so as to leave a small opening between the points, through which the ascending salmon enter. Partly from the inward pointing of the inscales, and partly from the instinct of the fish to ascend the river, they seldom get out again, and are easily caught. Frequently, weirs serve the purpose both of mill-dams and of fishing-weirs.

A weir sometimes made use of for catching salmon and other fish in tidal rivers, consists of a sort of horse-shoe shaped structure of loose stone-work, through which the water can percolate freely, with its heel or open end pointing up-stream. The fish ascend the river with the flood-tide, and falling back with the ebb, part get embayed within the walls at low water, and are either left dry, or are shut in so as to be easily caught.

Weirs, either of stone or of wicker work, are also sometimes made use of as an accessory to what in English fishing-rivers are called putts and putchers, being a sort of combination of wooden gratings acting something like those of the cruive and network; and in many cases, weirs, either natural, as formed by rocks or islands, or strictly artificial, are used for catching fish by means of an attached pokenet extended by the current.

By the English common law, no fishing mill-dam or fishing weir is legal except it be ancient, and even an ancient fishing-weir must have a free gap, and every fishing mill-dam must have a proper fish-pass.

The following are provisions as to weirs in the English Salmon Fishery Act, 1861: For the purpose of clearly indicating the rights of mill-owners, &c., in the first place, the expression 'dam' is defined to mean all weirs and other fixed obstructions used for damming up water; 'fishing weir,' a dam used for the exclusive purpose of facilitating the catching of fish; and 'fishing mill-dam,' a dam used partly for facilitating the catching of fish, and partly for supplying water for milling, &c. (24 and 25 Vict. c. 109, s. 4).

The following regulations are to be observed with respect to dams: No dam, except such fishing weirs and fishing mill-dams as were lawfully in use on the 6th August 1861, by grant, charter, or immemorial usage, must be used for facilitating the catching of salmon. Any proprietor of a fishery, with the consent of the Home Office, may attach to every dam which existed on the 6th of August 1861, such a fish-pass as the Home Office may approve, so that no injury be done to the milling power, or to the supply of water to or of any navigable river, canal, or other inland navigation. Every person who, in waters where salmon are

found, constructs a new dam, or raises or alters, so as to create increased obstruction to fish, a dam already constructed, must attach and maintain in an efficient state such a fish-pass as may be determined by the Home Office. By the Tweed Act, mill-dams, weirs, cauda, and other permanent obstructions are to be so constructed as to permit the free run of salmon in the ordinary state of the river. In Ireland, as in England, weirs are legal, if they can be traced back to statute 25 Edward III. Special Fishery Commissioners have power to inquire into legality of all fishing weirs, and every fishing weir must have a free gap.

By the old Scotch law, a provision as to mill-dams is given in the Act 1696, as follows: 'In respect that the salmon-fishing within the kingdom is much prejudiced by the height of mill-dams that are carried through the rivers where salmon are taken, His Majesty, with consent of the Estates of parliament, orders a constant slope in the mid-stream of each mill-dam dyke; and if the dyke be settled in several grains of the river, that there be a slope in each grain (except in such rivers where cruives are settled), and that the said slope be as big as conveniently can be allowed, providing always the said slope prejudice not the going of the mills situate upon any such rivers.' Cruives are by various old acts declared to be illegal in tidal waters, except the cruives and yairs of the Solway, which is exempted as being a Border river.

By the Scotch Fishery Act of 1862, the commissioners are empowered 'to make general regulations with respect to the construction and alterations of mill-dams, or lades, or water-wheels, so as to allow a reasonable means for the passage of salmon;' and they made a by-law, which has been sanctioned by the Home Secretary, providing that every dam should have a salmon pass or ladder, and also making provision for hecks at the intakes and lower ends of mill-lades, and immediately above the wheels, and regulations whereby the water, when not used for the mills, should be sent down the natural channel of the river. The commissioners are also required to make, and have made, general regulations as to the construction and use of cruives, which implies their legality, but only where there is a prescriptive right.

WELLINGTON, a town of New Zealand, the capital of a province of the same name, and now also the capital of the whole colony, the residence of the governor, and place of meeting of the 'General Assembly,' or colonial parliament. W. is beautifully situated on a bay of Port Nicholson, itself an inlet of Cook's Strait, on the southern coast of the North Island. The surrounding country is richly wooded, but the dense forests have begun to yield to the axe of the settler. W. is rapidly rising in importance, and has many good public buildings. In June 1866, a regular line of steam-packets was established between Sydney, W., and Panama. W. is also connected by steamers with all the principal ports of New Zealand.

WHITTINGTON, RICHARD. As the existence of this, for his time, remarkable man, is by many supposed to be as mythical as that of *Blue Beard* and *Jack the Giant-killer*, it has been thought not out of place here to state briefly the few authentic facts of his life. W. was descended from a good Gloucestershire family, and was born probably about 1360, the younger son of Sir William Whittington, who possessed the estate of Pauntley in that county. His father died not long after W. was born, and as his mother in a short time married again, Richard, who had no fortune, set out for London, to endeavour to make one by means of trade. That he left London

on account of ill-usage, but was induced to return by his interpretation of the friendly sound of Bow Bells, and that he afterwards made his living through the instrumentality of a cat, are stories not improbable, but which cannot be well authenticated. He appears, however, to have apprenticed himself to a mercer, and to have rapidly risen in the world. It is not known at what date he set up for himself, but we find him a member of the Mercers' Company in 1392, in which year he was elected an alderman of the city, and in the following year was appointed sheriff. In 1398, W. was elected Lord Mayor of London; was again chosen to fill that office in 1406; was elected member of parliament for the city in 1416; and in 1419, for the third time, filled the office of Mayor. These statements accord with the popular story of W.'s having been 'thrice Lord Mayor of London,' although some antiquaries doubt if he filled that office oftener than twice. W., on account of various services rendered to Henry V., received from that sovereign the honour of knighthood. We are not informed of the date of W.'s marriage; but from various authentic sources we learn that his wife's name was Alice, daughter of Sir Hugh Fitzwarren. She appears to have died several years before her husband, and to have left no issue. W. died in the spring of 1423, aged about 63 years. There can be no doubt that W. was diligent and exceedingly prosperous in business, upright and liberal in character—'a virtuous and godly man, full of good works (and those famous)'—and in many respects considerably in advance of his time. His liberality appears to have been unbounded. He lent large sums to his sovereign, which, according to some authorities, he did not ask back again. He took great interest in, and spent much money on the general improvement of London; was so far ahead of his age as to erect a public drinking-fountain; rebuilt, on a much better plan, the prison of Newgate; founded the library of the Greyfriars' Monastery in Newgate Street; restored the Hospital of St Bartholomew in Smithfield; rebuilt the Church of St Michael, in which he founded a college; 'beside many other good works.' In short, W. appears to have made it the chief aim of his life to discover and supply all the legitimate wants of his less fortunate fellow-men. At his death, he left the bulk of his property to be laid out in purposes of charity, and in completing those works which had been commenced under his own superintendance.—For proofs of all the above statements, which have been well authenticated, and for further details concerning the life of this remarkable man, we refer the reader to the Rev. Samuel Lysons's *Model Merchant of the Middle Ages* (Lond. 1860), an admirable and judicious biography of W.; also to various volumes of *Notes and Queries*.

WILKINSON, SIR JOHN GARDNER, a distinguished traveller and archaeologist, is the son of the late Rev. John Wilkinson, of Hardendale, in Westmoreland, and was born on the 5th of October 1797. Having lost both his parents at an early age, he was left under the guardianship of the Rev. Dr Yates, by whom he was sent to Harrow School in 1813, and to Exeter College, Oxford, three years later. While a boy, young W. had a strong desire to enter the navy, principally with a view to seeing foreign countries. He also in early life shewed a great fondness for architecture and sculpture. While at Harrow, he made sketches of all the churches within a radius of some miles from the school; and while at Oxford, often employed himself in drawing from the objects contained in the Arundel Collection. He still further cultivated his taste for architectural antiquities by trips on the continent made during

his college vacations. On taking his B.A. degree, he resolved upon making a wider tour on the continent. While in Italy, he became acquainted with Sir W. Gell, who, perceiving his taste for archaeological research, strongly urged him to make an extensive survey of the remains of Egyptian civilisation; and in October 1821, he set out for Alexandria, as a starting-point for his explorations. He took up his abode at Cairo, where he learned Arabic, both to read and speak; he also studied Coptic. Making Cairo his head-quarters, he now travelled through and investigated almost every part of Egypt and Lower Nubia. Twice he ascended the Nile as far as the Second Cataract, and several times as far as Thebes. At the latter famous site, he spent more than 12 months in making explorations; he also visited the deserts on either side of the river, and the Egyptian oases. During subsequent visits, he completed the exploration of those deserts, and, in fact, made a complete survey of Egypt, on a scale of about ten inches to a degree, which unfortunately, for the interests of science, has not yet been published. The same might have been the case with his *Survey of Thebes*, had not the author engraved and published it at his own expense. As a result of his first visit to Egypt, W. transmitted to the British Museum more than 300 antiquarian objects, besides numerous specimens of natural history. W.'s first residence in Egypt extended over a period of twelve years, during which time he composed and published his first two works on Egyptian subjects—viz., *Materia Hieroglyphica; containing the Egyptian Pantheon and the Succession of the Pharaohs, from the Earliest Times to the Conquest by Alexander, and other Hieroglyphical Subjects: with Plates and Notes explanatory of the same*. The preface to this work is dated 'Pyramids of Gezeh, July 1828;' but it was printed and revised for the author at Malta in the same year. This work was followed by *Extracts from several Hieroglyphical Subjects, found at Thebes and other parts of Egypt, with Remarks on the same*—also printed at Malta in 1830, but with a dedication to Sir W. Gell, dated 'Thebes, 1827.' In the same year (1830), he published his *Topographical Survey of Thebes, Tapt, Thaba, or Diospolis Magna*, in six sheets. In 1833, W., in consequence of ill health, was obliged to return to England. In 1835, he published *Topography of Thebes, and General View of Egypt* (Lond. John Murray). This was followed in 1837 by *Manners and Customs of the Ancient Egyptians, including their Private Life, Government, Laws, Arts, Manufactures, Religion, and Early History; derived from a Comparison of the Paintings, Sculptures, and Monuments still existing with the Accounts of Ancient Authors: illustrated by Drawings of those Subjects*. (3 vols. Lond. John Murray). This work at once obtained great popularity, both from the extent and soundness of its information, and the agreeable style in which it was written. It was highly spoken of by the critics; and obtained for him also the honour of knighthood, with which he was invested in 1839. Many things of importance were, however, omitted in it, which he afterwards published in *A Second Series of the Manners and Customs of the Ancient Egyptians, including their Religion, Agriculture, &c.* (2 vols. and a volume of plates, Lond. Murray, 1841). W. again visited Egypt in 1841 and in 1843. He also visited Syria, Constantinople, Tunis, and Sicily, returning to England after an absence of two years, by the Illyrian coast of the Adriatic. During his two years' absence, he also visited Dalmatia and Montenegro, which gave occasion to the publication of his *Dalmatia and Montenegro, with a Journey to Mostar, in Herzegovina, and*

Remarks on the Slavonic Nations; the History of Dalmatia and Ragusa; the Uscoes, &c. (2 vols., Lond. Murray). W.'s other works are—*Modern Egypt and Thebes; being a Description of Egypt, including the Information required for Travellers in that Country; with Wood-cuts and a Map* (2 vols., Lond. Murray, 1843); *Hand-book for Travellers in Egypt; new edition condensed of Modern Egypt and Thebes* (Lond. 1847, and again in 1858); *The Architecture of Ancient Egypt, with a Large Volume of Plates Illustrative of the Subject* (Lond. 1850); *The Fragments of the Hieratic Papyrus at Turin, containing the Names of Egyptian Kings, with the Hieratic Inscription at the Back* (Lond. 1851); *A Popular Account of the Ancient Egyptians, revised and abridged from his larger Work* (Lond. 1854); *The Egyptians in the Time of the Pharaohs; to which is added an Introduction to the Study of Egyptian Hieroglyphs*, by S. Birch (Lond. 1857), published as a companion to the Crystal Palace guides: *On Colour, and on the Necessity for a General Diffusion of Taste among all Classes; with Remarks on laying out Geometrical Gardens: illustrated by Coloured Plates* (Lond. 1858). W. also contributed notes to *The History of Herodotus—a New English Version, edited, with Copious Notes, by George Rawlinson, M.A., assisted by Col. Sir H. Rawlinson and Sir J. G. Wilkinson* (Lond. 1858, and again in 1862). In 1848, he paid a fourth visit to Egypt, and a fifth in 1855, when, as he was drawing at Thebes under excessive heat, he received a *coup de soleil*, which compelled him to return home. During late years, W. has occupied himself in examining ancient British remains in England and Wales. The results of his investigations he has occasionally made known in the Transactions of learned societies.

WOMEN'S RIGHTS. In 1851, an article in *The Westminster Review* attracted attention to the novel subject of the enfranchisement of women. Since that time, the agitation for women's rights has in this country, and to a still greater extent in America, attained the dimensions of a political movement. The subject has therefore become one of general interest. The following is an account of the claims included in women's rights, and a brief statement of the chief arguments by which those claims are supported.

1. *The Political Rights of Women.*—The discussion has hitherto turned upon the right to the suffrage. The right to vote is claimed in accordance with the principles of political reasoning that are held conclusive in the case of men. The argument applies with peculiar force to a democratic constitution. Democracy involves two ideas. It is a protest against privilege and against despotism; it maintains that every individual is born with an equal right to the protection and consideration of the law; and it affirms that every one must have a vote in order to secure this fundamental right. The practice of the United States shews a gradual approach to those principles. Till lately, the negroes were refused the benefit of them; but the privilege founded on colour has perished, and there remains now only the privilege founded on sex.

In England, the right to vote has been made to rest on the principles of English law. A petition of women to the House of Commons, presented on 7th June 1866, sets forth, that the possession of property in this country carries with it the right to vote in the election of representatives in parliament. From the earliest times, the principle of the English constitution, and the spirit of the English people, have required that no man's property should be taken for the purposes of government without his consent. Since, therefore, the English law

permits women to hold and manage property, it seems anomalous and inconsistent that it should refuse them a vote to protect their property from inordinate taxation. Other persons allowed by the law to hold property, but excluded from the suffrage, are minors, idiots, lunatics, and criminals. But the principle of disqualification in those cases does not apply to women. Moreover, there is alleged to be historical evidence that women have voted both in counties and boroughs. The disuse of the privilege is traced to historical causes. Such was the violence of the time, that women were often unable to administer their property, and it was therefore natural that they should take little part in elections. Besides, the right to vote was at first regarded, not as a privilege, but as a burden; for the power of the Commons was low, and the expense of paying members of parliament was considerable. The disfranchisement of women is therefore held to be an anomaly in the constitution, as it was an accident in history.

The objections to female suffrage are various. In an argument in the *Times*, it is said: 'There exists, as it were, a tacit concordat guaranteeing to the weaker sex the protection and deference of the stronger, upon one condition only: that condition is the political dependence of women.' This asserts a claim on the part of men to make laws for women, in return for protection and deference. Now, protection to person and property every one has a right to who obeys the laws and contributes to the support of the government. The reason for refusing votes to women must lie deeper. It may be said that, inasmuch as women are weak and at the mercy of men, men abstain from abusing their superiority only on one condition; that condition is, that women shall have no legal rights except those that men are pleased to give them. In the last resort, the rights and privileges of any class of men depend on their might. The nobility established their privileges when they had power. The working-class has been admitted to the franchise because its power has increased. But women have no physical power to enforce their rights. If rights are to be measured by might, women will occupy the bottom of the scale. This is their position among savages. But, as civilisation has advanced, men have learned to renounce the advantage of their physical superiority, and freely to give women privileges that could not have been extorted. It would therefore seem that the rights women actually enjoy do not depend upon, and are not to be measured by, their physical strength. The rights of women flow from the prevailing sense of justice, and justice now means that the interests of women be consulted with as much impartiality as the interests of men. An unjust preference of either would be mischievous to both. Since, then, the interests of women should be fairly considered, what reason can there be to prevent them voting, and thereby intimating what views they take of their own interests?

Another objection to the enfranchisement of women is, that women have no business with politics, and that politics would withdraw them from their proper duties. Is this apprehension well founded? Granting that domestic life is the proper sphere of women, is it really impossible to unite an interest in politics with attention to a family? Upon this subject, we are not altogether without experience. In the great dissenting churches in Scotland, women, though excluded from office, vote equally with men in the appointment of ruling-elders, ministers, and in everything that is decided by a popular vote. But this privilege has not 'hardened' them, or made them 'unfeminine,' or interfered with their

household work. On the other hand, it has largely contributed to the success of the voluntary system, and to the strength of the church. The chimerical nature of the alarm felt on this subject has been illustrated by the objections that might be made against allowing clergymen to vote. 'We should be told that clergymen have no business with politics; that it was their province to attend to spiritual matters, and that they ought to confine themselves to their proper sphere; that if they were permitted to participate in political affairs, it would deteriorate from the sanctity of their character; that the passions roused by political contests were inconsistent with that spirit of meekness and holiness which we look for in preachers of the gospel.' Women are not wholly excluded from politics. In some countries, a woman may be sovereign; and history affords many examples of women that have had the highest capacity for government. Women in this country, if they have the same qualification as men, have parochial votes. And few would go so far as to propose that women should not only be shut out from public affairs, but also be kept ignorant of politics. Even if family-life be made their sole occupation, it surely is not to bound the horizon of their knowledge and sympathies.

The remaining objections may be taken together. They are of the same kind as those recently employed against the enfranchisement of the working-class. They are briefly: That the interests of women are not neglected, for they are represented by their male connections; that women are ignorant of politics; that they would be exposed to intimidation at home, and to violence at the polling-booths; and lastly, that women do not want votes. It is not allowed that women are sufficiently represented by their male connections. Such indirect influence is not considered, in other cases, to be a reason for withholding the suffrage. Rich men have a great indirect influence, but they have also votes. It is an old argument, that operatives were represented by their employers; but that argument never convinced the operatives, and it has now ceased to affect the legislature. Why, then, should a *vicarious* representation, which is repudiated by every class of men, be considered sufficient for women? On the contrary, if women had votes, their interests would be better attended to, because no member can disregard with impunity any important section of his constituents. It would be the policy of statesmen to devise and carry out measures for their benefit.

But, it is said, women are ignorant of politics. This objection has lost much of its weight, now that household suffrage has been established. Educated women are surely not behind many of the new voters in political knowledge. Still, women, in general, know less of politics than men. They are constantly told that politics form no part of their business, and their opinions, like those of non-electors, have little direct and palpable influence on affairs. Political knowledge generally follows political power. Women have not the stimulus that acts on men; they have not the knowledge that their opinions form part of the legislative power.

There is little reason to fear that the possession of a vote would expose women to coercion and improper influence. The law has already defied a more serious danger. It permits women, and by special arrangement, even married women, to hold property, and it trusts its ability to protect them from the importunities of relations. If women can defend their property from greedy relatives, they will be no less able to give independent votes. The objection that women would be exposed to violence at

the polling-booths, is not formidable. If such were the fact, it would be no argument against female suffrage; it would be an argument against polling-booths. Should the police, however, be unable to protect female voters, there is the easy resource of voting-papers, already in use in the elections in the English universities.

The last objection is, that women do not want votes. A large number petitioned the Commons in favour of extending the franchise to women that possessed a household qualification; those petitioners represent a very much larger number, who are kept back by the various social checks that prevent women taking part in political agitation. Nor can there be any doubt that a proposal that makes way with men simply on the ground of justice, will find still more favour with women, since their interest is ranged on the same side.

The claim of women to the suffrage is not without support from practical considerations. History teaches that women must have votes in order to protect their interests; men, through all the vicissitudes of history, have shewn a constant preference of their own interests. In the words of Lord Macaulay: 'If there be a word of truth in history, women have been always, and still are, over the greater part of the globe, humble companions, playthings, captives, menials, beasts of burden. Except in a few happy and highly civilised communities, they are strictly in a state of personal slavery. Even in those countries where they are best treated, the laws are generally unfavourable to them, with respect to almost all the points in which they are the most deeply interested.'

In this country, women suffer from serious grievances. They are excluded from the universities, and no provision is made to give them the high education that men value. In consequence of this, men enjoy almost a monopoly of educated labour. Most of the charitable endowments for education in England were destined by the founders for girls as well as boys; but they have been generally appropriated to boys. Christchurch Hospital was intended for boys and girls; it educates 1100 boys and 26 girls. Women also are excluded from the professions and the higher branches of industry. The situation of a governess is almost the only one open to educated women; from other occupations they are shut out, partly by rules, partly by neglected education.

The law is unfair to women, especially the law of marriage. Marriage is constituted by free consent, and is supposed to imply the approval of both parties. Now, it would be a hard bargain, where one of the parties was offered all the terms of it in the lump, and was therefore obliged to take everything or reject the whole; yet all the incidents of marriage, all the terms of the contract, are fixed by the law, and the law is made by men. In constituting the relation of marriage—a relation of even greater importance to women than to men—women have no voice, they have only a barren and impracticable veto. The result is familiar to every lawyer. By the law of England, the custody of a woman's children, after seven years of age, belongs exclusively to her husband; after they reach that age, she has no right even to see them. The common law strips a woman of her property, and leaves her fortune at the mercy of her husband; the husband also can seize his wife's earnings, unless she is protected by a judicial separation, or by an order from a magistrate. A married woman cannot enter into contracts. In practice, this bad law is avoided by settlements made before marriage; but this protection involves expense, and is in a great measure confined to the rich. More recent

legislation is as unfair as the older law. In 1857, the Divorce Court was established, and it was enacted that, for adultery on the part of a wife, the husband could obtain a divorce; but for the adultery of a husband, a wife was not allowed a divorce. In addition to adultery, the husband must be guilty of cruelty or desertion. This inequality goes to the root of the marriage-contract: it means that, in consideration of maintenance, a woman gives her person to her husband, and therefore, unless she is ill-used or abandoned, she gets in substance what she bargained for. The law is severe on offences against property; it is comparatively lenient in punishing brutal assaults by husbands on wives; garroters are flogged, but not wife-beaters. Finally, in the words of Lord Brougham: 'There must be a total reconstruction of the law, before women can have justice.'

2. *The Industrial Rights of Women.*—These embrace admissibility to all offices, occupations, and professions; also admission to the universities, or some adequate provision for the education of women so as to fit them for high posts. This raises the question of the proper sphere of women. The prevailing ideas point to marriage as the true, if not the sole end of a woman's existence; but this theory is inadequate to meet our social difficulties. Many women are unmarried. What is to be done with them? To hinder them from doing the best they can for themselves, would be a manifest injustice; therefore, in the interests of single women, all occupations should be open. But the claims on behalf of women do not stop there. It is denied that men have any right to exclude women from active life, and so drive them into marriage as their only livelihood. On grounds of justice, the right of women to enter into industry is conceived as almost too clear for argument.

The objections to the Industrial Rights of Women must be noticed briefly. It is said that the proper sphere of woman is domestic life, and that she is by nature unfit for the struggles of industry. It appears from the census that just one half of women above twenty years of age are confined to domestic life. About a third of the adult female population are either of independent means, or support themselves by non-domestic industry; the rest occupy a secondary position in the industrial world, by assisting their husbands in business. But though the number of women engaged in industry is great, they are confined to poorly paid occupations, and their labour is for the most part unskilled. Generally speaking, the women of the middle class take no part in industry. The real issue is therefore narrow. It is not, shall women be admitted to industry? for that is settled; but, shall skilled and educated female labour be allowed? There is no evidence that women have no capacity but for the meanest employments. What they are fit for, can be finally determined only by actual trial. All that the advocates of women's rights ask is, do not anticipate the result, or foreclose the experiment. Some think that while it is desirable women should not be left unoccupied, they should not be admitted to industrial occupations, but society should seek a field for unmarried women in some works of charity or religion, or in some semi-domestic pursuit. This proposal is an attempt to establish, in this country, that provision for unmarried women that is supplied by the monastic system in Roman Catholic countries. The objection to it is clear. If this semi-domestic pursuit is the most agreeable and lucrative to women, they will, of course, hail the discovery of it with gladness; but if it is not, they may decidedly object to make martyrs of themselves.

A common objection is, that to take women from domestic work would harden them, and destroy the peculiar traits of their character. Now, a great part of what used to be the work of the household has passed to another province, spinning, weaving, brewing, and baking were at one time domestic work. If women are to do their ancient customary work, they must follow it abroad. Those who believe that the peculiar attributes of women are an artificial product of civilization, may feel alarmed at any disturbance of the present condition. But the genuine distinctions between the sexes flow from organisation, and will not be obliterated by similarity of education and employment; on the contrary, no feminine charm would be lost, but women would be more spirited, more intelligent, and fitter companions for men.

It is an argument sometimes relied upon, that an admission of women to industry would be prejudicial to men, because it would increase the supply of labour, and thereby lower the rate of wages. This objection is founded on the principle, that, when the wage-fund is constant, the rate of wages falls as the labourers are more numerous, and rises as they become less numerous. But the competition of women is, to some extent, an exception, for if they do not work for themselves, they must be supported out of the wages of men. If, however, wages were to fall below the ordinary standard of comfort, the tendency would be, by fewer births or emigration, to reduce the excess of labourers, till the supply of labour should be adjusted to the required standard of wages; and experience shows that wages are not permanently lowered by the admission of women to industry. In the working-class, wages adjust themselves to a scale enabling a working-man to maintain a wife and family.

In the last place, it is said that active life is inconsistent with the cares of maternity. This, of course, has no application to the large class of childless women; and there can be no necessity for prohibiting women from entering into industrial life, if their situation renders it impracticable. The incompatibility between active life and maternity may safely be left to look after itself. From the returns in the census, it appears that one out of eight married women are employed in non-domestic labour; but, since many of their occupations are not incompatible with household duties, and since many have no children to attend to, it seems probable that only among a small number of the working-class, the duties of maternity are sacrificed to out-door employment. It is, however, a moot-point how far maternity interposes a barrier to the industrial education and employment of women. In the working-class, the mother usually nurses her children, for she could seldom make a profit by engaging in another employment, and hiring a servant; but if women were employed in skilled and well-paid occupations, they would probably leave nursing, which at present is unskilled labour, to servants. The solution of the problem must, however, be left to trial and experience. One principle, at any rate, is clear; except in so far as women are occupied as mothers, they should be employed in the most remunerative work. That would be beneficial to men, for it would relieve them of a pecuniary burden; it would be beneficial to women, for it would make them independent.

The women of the middle class, led astray by a mistaken aspiration to aristocratic leisure, have held aloof from the struggles and rewards of industry. This operates injuriously in various ways. It creates an unnatural competition with working-women, as in needle-work. Middle-class women

often discharge duties that might well be left to upper servants. If they entered into commerce and trade, they would fit themselves for, and require, a higher kind of occupation than those thankfully accepted by poor and untaught women. At present, the higher walks of business, and even subordinate offices of trust and skill, are monopolised by men; hence women engaged in the lower employments derive little pecuniary benefit from trustworthiness, experience, or judgment, and have no hope of rising. If they should attempt to better their condition, they are left without encouragement or support. The exclusion of women of the middle class from industry is hurtful to themselves. It often leads to poverty of the bitterest kind—the poverty of gentlemen. It leaves them without occupation, a prey to *ennui* and bad health. It also forbids perfect companionship and sympathy between the sexes. The whole scope of a man's education is towards industry. In it he lives, and moves, and has his being. But of this world, women have no direct knowledge. Hence a want of intellectual sympathy between men and women, and an absence of any common standard of reasoning and evidence. Nor is this all. The virtues upon which industrial and public life repose, do not derive due support from women. They are ignorant of the difficulties that beset moral problems under circumstances of which they have no experience, and their moral wisdom can hardly go beyond traditional saws. Indeed, their influence is sometimes on the wrong side. A man will be reluctant to injure his family in their pecuniary interests, for some point of conscience that his wife does not sympathise with, or for objects that she does not understand.

No account of women's rights would be complete without some notice of the claim to equality in marriage. This is the goal to which history points. 'Among tribes which are still in a primitive condition, women were and are the slaves of men for purposes of toil. All the hard bodily labour devolves on them. In a state somewhat more advanced, as in Asia, women were and are the slaves of men for purposes of sensuality. In Europe, there early succeeded a third and milder dominion, secured, not by blows, nor by locks and bars, but by sedulous inculcation on the mind; feelings also of kindness, and ideas of duty, such as a superior owes to inferiors under his protection, became more and more involved in the relation. But it did not for many ages become a relation of companionship, even between unequals.' That stage has now been attained, and, 'for the first time in the world, men and women are really companions.' Women cannot be good companions for men unless they are equals. If they are kept inferior in education and knowledge, their influence will tend to drag men down to their own level. Nor is it enough that women should be taught merely to talk about the subjects that interest men, for the intercourse that is of value is not intercourse between an active and a passive mind, but between two active minds. The theory of the subordination of women—that woman was made for man, and man was made for himself—involves several bad consequences; for women being unable to attain their ends directly, have recourse to management and artifice. It is a theory that almost forbids the existence of public spirit in women. Hence their influence is not so great as might be supposed in counteracting selfishness. The effect is to substitute for the selfishness of the bachelor the selfishness of the family man.

The general movement of society is from subordination to equality. Under the feudal system, society was constituted on the principle of subordination. The land was tilled by serfs, and there

were few but said that serfdom was the natural position of a creature so low as an agricultural labourer. But serfdom did not endure, and we have learned that it is happier for all parties that the land should be tilled by freemen. And now, too, negro slavery, the most plausible form of slavery, has been abolished. The tendency of social changes is towards equality, as the most satisfactory relation between man and man; it also seems to point to equality as the highest relation between man and woman.—The subject of women's rights is discussed in the following: *Dissertations and Discussions*, by J. S. Mill, vol. ii., 'Enfranchisement of Women'; *The Political and Social Dependence of Women*, 1867; *The Industrial and Social Position of Women*, 1857; Speech by J. S. Mill in House of Commons, May 21, 1867; *The Westminster Review*, January 1867, article 'The Petition of the Ladies.'

WORKSHOP REGULATION ACT, 1867 (30 and 31 Vict. c. 146) is an important act for regulating the education of children, and the hours of labour for children, young persons, and women who are employed in places not subject to the Factory Acts. It extends to all such persons employed upon any handicraft, in any workshop. Its application is wide, as the definition of a 'handicraft' includes every species of manual labour exercised for gain, and that of a 'workshop' includes every place, whether open or under cover, where any such handicraft is carried on, 'and to which, and over which, the person by whom such child, young person, or woman is employed, has the right of access and control.' The principal provisions of the act as to the hours of labour are: (1) That no child under the age of eight shall be employed in any handicraft in any workshop; (2) that no child under thirteen shall be employed for more than six hours and a half each day, or before 6 A.M., or after 8 P.M.; (3) that no young person under eighteen, and no woman shall be employed more than 12 hours out of any period of 24 hours, or shall be employed between 9 P.M. and 5 A.M., and that the intervals for meals and rest shall not be less than an hour and a half in all; (4) that, except in retail establishments employing not more than five persons, no such child, young person, or woman shall be employed after two o'clock on Saturday, and that in no case shall they be employed on Sundays; and (5) that no child under eleven shall be employed in grinding in the metal trades or in fustian-cutting. From these general rules, the act itself makes a few exceptions, and a limited power is given to the Home Secretary to make others. The regulations as to education are: (1) That every child under thirteen, who is employed in a workshop, shall attend school for at least 10 hours in every week during the whole of which he is so employed; and (2) that in computing the time at school, no time shall be included in excess of three hours at once, or of five hours in one day; or on Sundays; or before 8 A.M. or after 6 P.M. Non-attendance at school may be excused by sickness, or during holidays, or if there be no certified school within a mile of the workshop or of the child's residence. The inspector of factories certifies whether the school is sufficient. The obligation to carry out the regulations as to education, is laid (under penalties) both on the parent and on the employer; and the latter is authorised, on the application of the teacher, to pay him for the schooling a weekly sum out of the child's wages, not exceeding a twelfth part of them, and not exceeding twopence per week.

WORKSOP (anciently *Wirkenesop*), a town of Nottinghamshire, England, 24 miles north from Nottingham, on the right bank of the Ryton, a

branch of the Idle, and near the Chesterfield Canal, which communicates with the Trent. It is situated near the northern extremity of Sherwood Forest. The town is generally well built, and great sanitary improvements of drainage and sewerage have recently been effected. There is a fine old church in the Norman style, with two lofty towers. W. was formerly noted for its Augustine monastery, of which, however, there are few remains. Malting is carried on here to a very great extent. Much barley is grown in the neighbourhood. There is

some trade in flour, timber, &c. W. is also a station on the Manchester, Sheffield, and Lincolnshire Railway. Pop. (1861) 7112.

WUDWAN, a town of India, in the peninsula of Kattywar, province of Guzerat, 105 miles west-by-north from Baroda. It is situated on a small river, which falls into the great salt marsh known as the Runn of Cutch. Pop. 32,220. The surrounding district is in a high state of cultivation, and is celebrated for the excellence of the cotton which it produces.

X

XERES-DE-LA-FRONTERA, or **JEREZ-DE-LA-FRONTERA**, an important town of Spain, in the province of Cadiz, and 14 miles directly north-east-by-north from Cadiz, near the right bank of the Guadalete, and on the railway between Cadiz and Seville. The houses are generally well built, and the streets and squares clean, spacious, well paved, and well lighted. The wealthy wine-merchants mostly reside in the suburbs. X. is an ancient town, supposed by many to be the *Asta Regia Cæsariana* of the Romans. X. has manufactures of woollen cloth and leather, and a considerable trade in corn; but all these are of little consequence in comparison with its wine-trade. *Sherry* derives its name from Xeres-de-la-Frontera.

Some of its *bodegas*, or wine-stores, are of vast dimensions. They are not wine-vaults, but stores erected above ground. The greater part of the wine of X. is exported to England; and some of the principal wine-merchants are of French and Scottish extraction. Pop. (1860) 52,158.

XERES-DE-LOS-CABALLEROS, or **JEREZ-DE-LOS-CABALLEROS** (anc. *Esuris*), a town of Spain, in the province of Badajoz, and 40 miles south from Badajoz. X. is a picturesque old town, partly surrounded by a Moorish wall. The ecclesiastical edifices are remarkably numerous. There are manufactures of woollen and linen cloth. Amongst the chief articles of trade, besides the produce of the manufactures, are pigs and fruit. Pop. (1860) 8295.

Y

EA'DON, a town of the West Riding of Yorkshire, England, six miles north-north-east from Bradford. It stands on a hill, on the left side of the valley of the Aire. It has considerable woollen manufactures. Pop. (1861) 4109.

YO'RUBA, or **YARRIBA**, a country of Guinea, West Africa, lying to the east and north-east of Dahomey, in N. lat. 6°—9°, and E. long. 2°—6°. Its area is about 70,000 sq. m.; and the pop. is estimated at 2,500,000. Palm-oil, cotton, and ivory are the principal articles of export. **LAGOS** (q. v. in SUPPLEMENT) is the port through which trade with foreign countries is chiefly carried on. There are numerous large towns in Y., but the people are little if at all less barbarous in their customs than their neighbours of Dahomey.

YO-SEMITE, **YO-HAMITE**, or **AHWAHNE**, a valley and waterfall of California, in the east of the state, about 57 miles from Coulterville, on a large feeder of the San Joaquin, and on the western side of the Sierra Nevada. The scenery of California is remarkable for its combination of loveliness

with sublimity; and in no part of the country yet explored are these characters so strikingly displayed as in the Y. valley—a valley of from 8 to 10 miles long, and a little more than a mile wide; in some places filled with noble oaks, in others opening out into broad grassy fields; with a river rushing through it about 40 yards in breadth; pine-covered mountains towering with very steep slopes to the height of 3500 feet; a precipice or 'bluff' in one place rising perpendicularly 3089 feet above the valley; in another, a rock almost perpendicular, 3270 feet high; waterfalls pouring over its sides from heights of 700 to almost 1000 feet; and one great waterfall, broken into three leaps, but of which the whole height is 2550 feet. Of the other waterfalls on the sides of the valley, the Pohono, or Bridal Veil Waterfall, is particularly to be remarked for its beauty, as well as for its height, which is 940 feet, and quite unbroken. The Y. valley has begun to attract visitors since California has become peopled, and will probably soon have its hotels and guides, like the valleys of Switzerland and the Falls of Niagara.

Z

ZARSKOE-SELO, or **SAINT SOPHIA**, a town of Russia, in the government of St Petersburg, and 17 miles south from St Petersburg, with which it is connected by a railway. It has a college and a military school. The palace of Z is a summer residence of the emperor, founded by Peter the Great in 1710, and the favourite abode of Catharine II. The church of St Sophia is a miniature copy of the mosque of that name at Constantinople. Pop. (1863) 10,637.

ZNAIM, or **ZNAYM**, a town of the Austrian Empire, in Moravia, on a rising ground close to the left bank of the Taja, 48 miles north-by-west from Vienna. It is celebrated for the conflict which took place here between the French and Austrians, on June 14, 1809, in which the French were victorious (see **WAGRAM**). A castle on a height, the ancient residence of the princes of Moravia, is now a military hospital. Near it is a circular church, supposed to be as old as the 12th century. Pop. 8676.

ZOETROPE, or **WHEEL OF LIFE**, an optical instrument, so named from its exhibiting pictures of objects as if endowed with life and activity. Although only recently introduced to the public from America, under this name, the instrument itself, which is simply a cylindrical thaumatrope, was invented and made the subject of a patent so long ago as the year 1860. Mr Peter Hubert Desvignes, the inventor, in his published specification, has very fully described various modifications of the cylindrical thaumatrope; and the instruments which, under the name of Mimoscope, he contributed to the London Exhibition of 1862, being furnished with pictures of exquisite artistic finish and beauty, were deservedly rewarded with 'honourable mention.' Mr Desvignes also proposed a stereoscopic form of the instrument, in anticipation of the one already described under Stereoscope (q. v.), and has employed models, insects, and other objects, instead of pictures, with perfect success. The truly marvellous results shewn in this instrument depend, primarily, on the well-known fact, that vision 'persists' for a certain short interval of time after the occlusion of the visual ray. It follows from this principle, that, if

Fig. 1.

representing the different attitudes successively assumed by an object in completing a given movement, be presented to the eye so quickly that the visual impression of each picture shall continue until the incidence of the one next following, the object will remain constantly in view, and its various parts will appear to execute the movement delineated by the pictures. The mechanical means for effecting this result will be understood from fig. 1, which represents the zoetrope in its most popular, but by no

means most excellent, form. C, a cylinder of strong card-board, 12 inches in diameter, and $7\frac{1}{2}$ inches in depth, with a metal rim at the top, and fastened to a circular piece of wood, B. The latter is screwed at its centre to a pivot, P, which moves freely within the upright of the stand, S, and forms a vertical axis, round which the cylinder may be made to revolve with any desired rapidity; a, thirteen equidistant apertures, each $\frac{1}{4}$ inch in width, and 3 inches long. Each series of pictures is printed on a strip of thick paper, $3\frac{1}{2}$ inches in breadth, and 36 inches in length. In using the instrument, illuminate it well from above, and, having placed the picture-strip within the cylinder, immediately beneath the apertures, a, rotate the cylinder with the requisite velocity (which will vary according to the nature of the subject), and look through the apertures at the pictures upon the opposite side of the cylinder. To avoid the grotesqueness of a number of groups

all seen performing the same movement at the same time, Mr Desvignes devised the thaumatrope, shewn in a somewhat modified form by fig. 2, in which the cylinder, C, turns upon a horizontal axis, P; and by means of an aperture at the bottom of the hood, H, the sight is limited to the space occupied by a single group on the opposite side of the cylinder, and, both

Fig. 2.

eyes being brought into consentaneous activity, the clearness and pleasantness of the illusion are greatly enhanced. In this arrangement, the groups are arranged, on the strips, one above another, and not side by side, as in the former; and they are perforated with apertures to correspond with those on the cylinder. As has been pointed out by Mr Desvignes, the width of the apertures should never exceed one-sixteenth of an inch; and the exterior of the instrument should be painted mat black.

We will now speak of the principles which determine the character and distinctness of the illusion, and first of all, will endeavour to explain why it is that the pictures, looked at through the apertures, are plainly visible; whereas, viewed over the top of the revolving cylinder, they run into an indistinguishable mass.

The effect of the apertures, in this regard, is twofold; they limit the *time* during which each group is pictured upon the retina; and they limit, or should be made to limit, the *quantity* of each group at any one instant so depicted. Obviously, if the view be *instantaneous* only, the group in that minute interval of time will not have moved to a *perceptible* degree, and will therefore appear stationary. It is for this reason that the apertures should be made very narrow (not exceeding one-sixteenth of an inch, as above stated), and then, the eye being placed close to them, the retinal images will not be blurred—as with wider apertures, and consequent increased motion of the pictures while under view, they would

ZOETROPE.

be—and the maximum of *definition* is thus attained. But, in this case, both the quantity of light reaching the eye, and the time of its operation, are insufficient, which defects can only be compensated by setting the instrument in violent motion, thus occasioning an inconveniently rapid recurrence of the retinal impressions. Instead, therefore, of letting the whole picture be seen for a *single* instant, let us increase the total time of visibility by arranging that successive small portions of the pictures shall be seen in *successive* instants. This is effected by withdrawing the eye a few inches from the aperture; for the eye being at the apex of the visual angle, the further it is removed from the aperture, the greater is the distance *within the visual angle* through which the aperture must travel; and prolonged in a like degree will be the *total time of visibility* for each picture. But here another difficulty is evoked, manifesting itself in one of the most puzzling phenomena of this curious instrument. The pictures are seen as *sensibly diminished in breadth*, the explanation of which is as follows: The longer the time of visibility, the greater will be the onward movement of the picture while under view; therefore, if the left-hand side of the picture come first into view, by the time the advance of the aperture permits of the right-hand side being seen, the latter will have progressed *towards* the left, and it will accordingly be seen relatively nearer to the left side than is its natural position. And this com-

pression, of course, takes effect over the whole of the picture. In the exquisitely elaborate drawings prepared by Mr Desvignes, this compression was allowed for, to the great enhancement of the effect.

Lastly, of the effects due to the pictures themselves. If the pictures on the strip be the same in number as the apertures, the pictures will either coincide with the apertures, in point of position, or will be equidistant, each from its adjacent aperture; in which case there will be no apparent shifting of the pictures either to right or left. But if there be 12 pictures and 13 apertures, the picture-interval will be greater than the aperture-interval, and only one picture on the strip can be coincident with an aperture; the rest will be situated in advance of the apertures, each succeeding one slightly more than its predecessor; and, as a consequence, seen through the apertures of the revolving cylinder, they will appear continuously to advance. The contrary will be the case, if the number of the pictures exceed that of the apertures. These curious properties, which make it possible to exhibit figures moving either backwards or forwards, as well as with movements proper to themselves, were fully investigated by the late Professor Faraday; and we would recommend those interested in the subject to refer to his *Memoir on Optical Deceptions*, contained in his *Experimental Researches in Chemistry and Physics*, pp. 291, *et seq.*

INDEX

OF MATTERS NOT HAVING SPECIAL ARTICLES.

It has been thought unnecessary to repeat in the Index the titles of the 27,000 articles composing the body of the work. Any person consulting the Encyclopædia is supposed, in the first instance, to look for the subject he is in quest of in its proper alphabetical place. If it is not to be found there, by turning to the Index he is likely to get a reference to it under another name, or as coming in for notice in connection with some other subject. It frequently happens that subjects, having articles of their own, are further noticed under other heads; and where it seemed of importance, a reference is given in the Index to this additional information. The subjects treated in the Supplement, both principal and secondary, have also been incorporated in the Index, so as to prevent the necessity of further search.—The title of the article referred to is printed in *Italics*; and when the article is of considerable length, the page is given in which the information is to be found.

ABBREVIATIONS: *r.*, river; *L.*, lake; *Suppl.*, Supplement; *mt.*, mountain; *i.*, island; *c.*, cape.
